# 1 Overview

The MPC860 Quad Integrated Communications Controller (PowerQUICC™) is a versatile one-chip integrated microprocessor and peripheral combination designed for a variety of controller applications. It particularly excels in both communications and networking systems. The PowerQUICC unit is referred to as the MPC860 in this manual.

The MPC860 is a derivative of Motorola's MC68360 Quad Integrated Communications Controller (QUICC™), referred to here as the QUICC, that implements the PowerPC architecture. The CPU on the MPC860 is a 32-bit PowerPC™ core that incorporates memory management units (MMUs) and instruction and data caches and that implements the PowerPC instruction set. The communications processor module (CPM) from the MC68360 QUICC has been enhanced by the addition of the inter-integrated controller (I<sup>2</sup>C) channel. The memory controller has been enhanced, enabling the MPC860 to support any type of memory, including high-performance memories and new types of DRAMs. A PCMCIA socket controller supports up to two sockets. A real-time clock has also been integrated.

Table 1 shows the functionality supported by the members of the MPC860 family.

### 3 Maximum Tolerated Ratings

This section provides the maximum tolerated voltage and temperature ranges for the MPC860. Table 2 provides the maximum ratings.

This device contains circuitry protecting against damage due to high-static voltage or electrical fields; however, it is advised that normal precautions be taken to avoid application of any voltages higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced, if unused inputs are tied to an appropriate logic voltage level (for example, either GND or  $V_{dd}$ ).

**Table 2. Maximum Tolerated Ratings**

<sup>1</sup> The power supply of the device must start its ramp from 0.0 V.

<sup>2</sup> Functional operating conditions are provided with the DC electrical specifications in Table 5. Absolute maximum ratings are stress ratings only; functional operation at the maxima is not guaranteed. Stress beyond those listed may affect device reliability or cause permanent damage to the device.

**Caution:** All inputs that tolerate 5 V cannot be more than 2.5 V greater than the supply voltage. This restriction applies to power-up and normal operation (that is, if the MPC860 is unpowered, voltage greater than 2.5 V must not be applied to its inputs).

<sup>3</sup> Minimum temperatures are guaranteed as ambient temperature,  $T_A$ . Maximum temperatures are guaranteed as junction temperature,  $T_j$ .

## 7 Thermal Calculation and Measurement

For the following discussions,  $P_D = (V_{DD} \times I_{DD}) + PI/O$ , where PI/O is the power dissipation of the I/O drivers.

### 7.1 Estimation with Junction-to-Ambient Thermal Resistance

An estimation of the chip junction temperature,  $T_J$ , in °C can be obtained from the equation:

$$T_J = T_A + (R_{\theta JA} \times P_D)$$

where:

- $T_A$  = ambient temperature (°C)
- $R_{\theta JA}$  = package junction-to-ambient thermal resistance (°C/W)
- $P_D$  = power dissipation in package

The junction-to-ambient thermal resistance is an industry standard value which provides a quick and easy estimation of thermal performance. However, the answer is only an estimate; test cases have demonstrated that errors of a factor of two (in the quantity  $T_J - T_A$ ) are possible.

### 7.2 Estimation with Junction-to-Case Thermal Resistance

Historically, the thermal resistance has frequently been expressed as the sum of a junction-to-case thermal resistance and a case-to-ambient thermal resistance:

$$R_{\theta JA} = R_{\theta JC} + R_{\theta CA}$$

where:

- $R_{\theta JA}$  = junction-to-ambient thermal resistance (°C/W)
- $R_{\theta JC}$  = junction-to-case thermal resistance (°C/W)
- $R_{\theta CA}$  = case-to-ambient thermal resistance (°C/W)

$R_{\theta JC}$  is device related and cannot be influenced by the user. The user adjusts the thermal environment to affect the case-to-ambient thermal resistance,  $R_{\theta CA}$ . For instance, the user can change the air flow around the device, add a heat sink, change the mounting arrangement on the printed circuit board, or change the thermal dissipation on the printed circuit board surrounding the device. This thermal model is most useful for ceramic packages with heat sinks where some 90% of the heat flows through the case and the heat sink to the ambient environment. For most packages, a better model is required.

### 7.3 Estimation with Junction-to-Board Thermal Resistance

A simple package thermal model which has demonstrated reasonable accuracy (about 20%) is a two resistor model consisting of a junction-to-board and a junction-to-case thermal resistance. The junction-to-case covers the situation where a heat sink is used or where a substantial amount of heat is dissipated from the top of the package. The junction-to-board thermal resistance describes the thermal performance when most of the heat is conducted to the printed circuit board. It has been observed that the thermal performance of most plastic packages and especially PBGA packages is strongly dependent on the board temperature; see Figure 1.

Figure 1. Effect of Board Temperature Rise on Thermal Behavior

If the board temperature is known, an estimate of the junction temperature in the environment can be made using the following equation:

$$T_J = T_B + (R_{\theta JB} \times P_D)$$

where:

$R_{\theta JB}$  = junction-to-board thermal resistance ( $^{\circ}C/W$ )

$T_B$  = board temperature ( $^{\circ}C$ )

$P_D$  = power dissipation in package

If the board temperature is known and the heat loss from the package case to the air can be ignored, acceptable predictions of junction temperature can be made. For this method to work, the board and board mounting must be similar to the test board used to determine the junction-to-board thermal resistance, namely a 2s2p (board with a power and a ground plane) and vias attaching the thermal balls to the ground plane.

### 7.4 Estimation Using Simulation

When the board temperature is not known, a thermal simulation of the application is needed. The simple two resistor model can be used with the thermal simulation of the application [2], or a more accurate and complex model of the package can be used in the thermal simulation.

### 7.5 Experimental Determination

To determine the junction temperature of the device in the application after prototypes are available, the thermal characterization parameter ( $\Psi_{JT}$ ) can be used to determine the junction temperature with a measurement of the temperature at the top center of the package case using the following equation:

$$T_J = T_T + (\Psi_{JT} \times P_D)$$

where:

$\Psi_{JT}$  = thermal characterization parameter

$T_T$  = thermocouple temperature on top of package

$P_D$  = power dissipation in package

The thermal characterization parameter is measured per JEDEC JESD51-2 specification using a 40 gauge type T thermocouple epoxied to the top center of the package case. The thermocouple should be positioned so that the thermocouple junction rests on the package. A small amount of epoxy is placed over the thermocouple junction and over about 1 mm of wire extending from the junction. The thermocouple wire is placed flat against the package case to avoid measurement errors caused by cooling effects of the thermocouple wire.

## 8 Layout Practices

Each  $V_{DD}$  pin on the MPC860 should be provided with a low-impedance path to the board's supply. Each GND pin should likewise be provided with a low-impedance path to ground. The power supply pins drive distinct groups of logic on chip. The  $V_{DD}$  power supply should be bypassed to ground using at least four 0.1  $\mu$ F-bypass capacitors located as close as possible to the four sides of the package. The capacitor leads and associated printed circuit traces connecting to chip  $V_{DD}$  and GND should be kept to less than half an inch per capacitor lead. A four-layer board is recommended, employing two inner layers as  $V_{CC}$  and GND planes.

All output pins on the MPC860 have fast rise and fall times. Printed circuit (PC) trace interconnection length should be minimized in order to minimize undershoot and reflections caused by these fast output switching times. This recommendation particularly applies to the address and data busses. Maximum PC trace lengths of 6 inches are recommended. Capacitance calculations should consider all device loads as well as parasitic capacitances due to the PC traces. Attention to proper PCB layout and bypassing becomes especially critical in systems with higher capacitive loads because these loads create higher transient currents in the  $V_{CC}$  and GND circuits. Pull up all unused inputs or signals that will be inputs during reset. Special care should be taken to minimize the noise levels on the PLL supply pins.

## 9 Bus Signal Timing

Table 6 provides the bus operation timing for the MPC860 at 33, 40, 50, and 66 MHz.

The maximum bus speed supported by the MPC860 is 66 MHz. Higher-speed parts must be operated in half-speed bus mode (for example, an MPC860 used at 80 MHz must be configured for a 40 MHz bus).

The timing for the MPC860 bus shown assumes a 50-pF load for maximum delays and a 0-pF load for minimum delays.

**Table 6. Bus Operation Timings**

<sup>1</sup> Phase and frequency jitter performance results are only valid if the input jitter is less than the prescribed value.

<sup>2</sup> If the rate of change of the frequency of EXTAL is slow (i.e., it does not jump between the minimum and maximum values in one cycle) or the frequency of the jitter is fast (i.e., it does not stay at an extreme value for a long time) then the maximum allowed jitter on EXTAL can be up to 2%.

<sup>3</sup> The timings specified in B4 and B5 are based on full strength clock.

<sup>4</sup> The timing for  $\overline{BR}$  output is relevant when the MPC860 is selected to work with external bus arbiter. The timing for  $\overline{BG}$  output is relevant when the MPC860 is selected to work with internal bus arbiter.

<sup>5</sup> The timing required for  $\overline{BR}$  input is relevant when the MPC860 is selected to work with internal bus arbiter. The timing for  $\overline{BG}$  input is relevant when the MPC860 is selected to work with external bus arbiter.

<sup>6</sup> The D(0:31) and DP(0:3) input timings B18 and B19 refer to the rising edge of the CLKOUT in which the  $\overline{TA}$  input signal is asserted.

<sup>7</sup> The D(0:31) and DP(0:3) input timings B20 and B21 refer to the falling edge of the CLKOUT. This timing is valid only for read accesses controlled by chip-selects under control of the UPM in the memory controller, for data beats where DLT3 = 1 in the UPM RAM words. (This is only the case where data is latched on the falling edge of CLKOUT.)

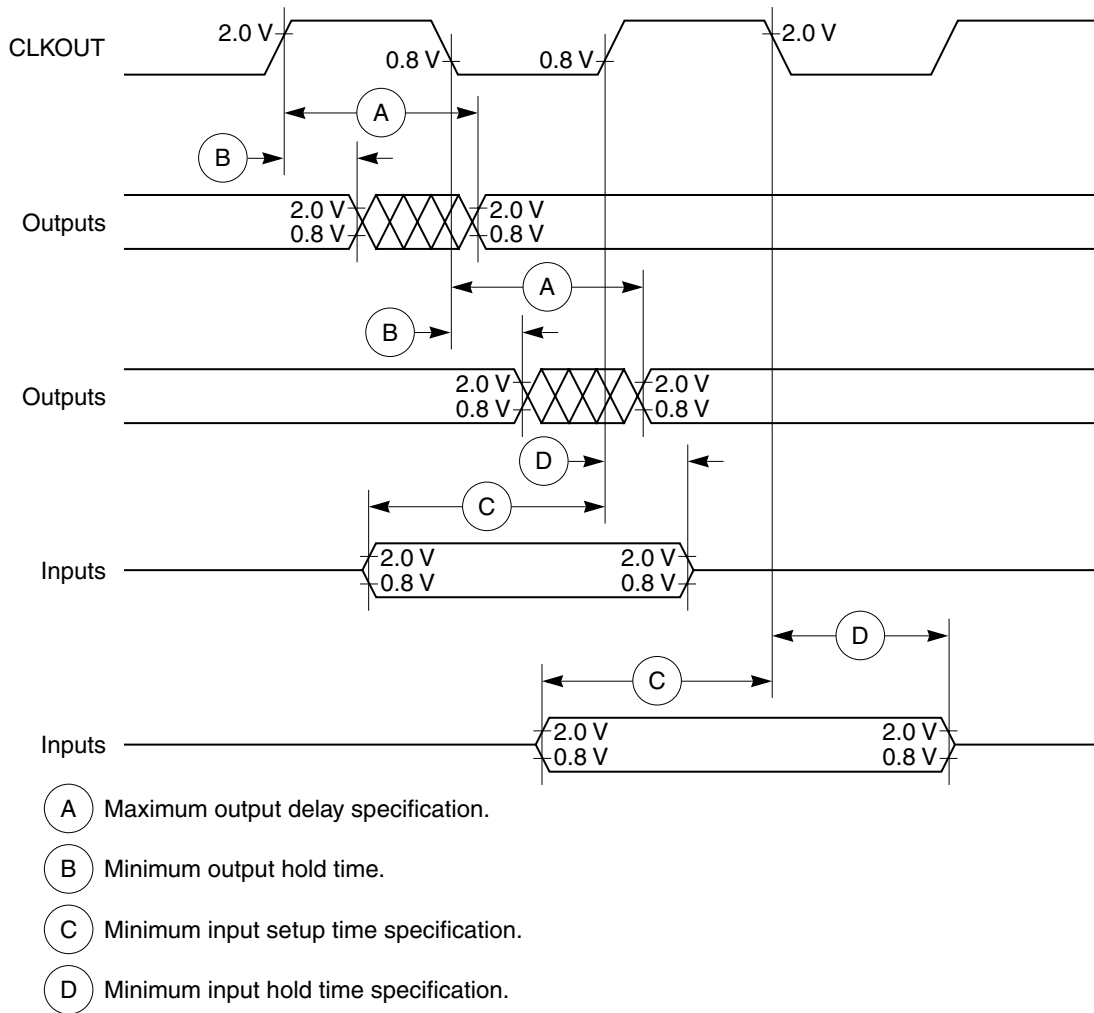

<sup>8</sup> The timing B30 refers to  $\overline{CS}$  when ACS = 00 and to  $\overline{WE}(0:3)$  when CSNT = 0.

<sup>9</sup> The signal UPWAIT is considered asynchronous to the CLKOUT and synchronized internally. The timings specified in B37 and B38 are specified to enable the freeze of the UPM output signals as described in Figure 17.

<sup>10</sup> The  $\overline{AS}$  signal is considered asynchronous to the CLKOUT. The timing B39 is specified in order to allow the behavior specified in Figure 20.

I39	$\overline{IRQx}$ valid to CLKOUT rising edge (setup time)	6.00	—	ns
I40	$\overline{IRQx}$ hold time after CLKOUT	2.00	—	ns
I41	$\overline{IRQx}$ pulse width low	3.00	—	ns
I42	$\overline{IRQx}$ pulse width high	3.00	—	ns

<sup>1</sup> The timings I39 and I40 describe the testing conditions under which the  $\overline{IRQ}$  lines are tested when being defined as level sensitive. The  $\overline{IRQ}$  lines are synchronized internally and do not have to be asserted or negated with reference to the CLKOUT.

The timings I41, I42, and I43 are specified to allow the correct function of the  $\overline{IRQ}$  lines detection circuitry, and has no direct relation with the total system interrupt latency that the MPC860 is able to support.

## 13 FEC Electrical Characteristics

This section provides the AC electrical specifications for the Fast Ethernet controller (FEC). Note that the timing specifications for the MII signals are independent of system clock frequency (part speed designation). Also, MII signals use TTL signal levels compatible with devices operating at either 5.0 V or 3.3 V.

### 13.1 MII Receive Signal Timing (MII\_RXD[3:0], MII\_RX\_DV, MII\_RX\_ER, MII\_RX\_CLK)

The receiver functions correctly up to a MII\_RX\_CLK maximum frequency of 25 MHz +1%. There is no minimum frequency requirement. In addition, the processor clock frequency must exceed the MII\_RX\_CLK frequency – 1%.

Table 27 provides information on the MII receive signal timing.
