

Features

- Automatic power-down when deselected
- CMOS for optimum speed/power
- High speed
— 25 ns
- Low active power
— 440 mW (commercial)
— 605 mW (military)
- Low standby power
— 55 mW
- TTL-compatible inputs and outputs
- Capable of withstanding greater than 2001V electrostatic discharge

Functional Description

The CY7C147 is a high-performance CMOS static RAMs organized as 4096 words by 1 bit. Easy memory expansion is provided by an active LOW chip enable (\overline{CE}) and three-state drivers. The CY7C147 has an automatic power-down feature, reducing the power consumption by 80% when deselected.

Writing to the device is accomplished when the chip select (\overline{CE}) and write enable (\overline{WE}) inputs are both LOW. Data on the input pin (DI) is written into the memory loca-

tion specified on the address pins (A_0 through A_{11}).

Reading the device is accomplished by taking the chip enable (\overline{CE}) LOW while (\overline{WE}) remains HIGH. Under these conditions, the contents of the locations specified on the address pins will appear on the data output (DO) pin.

The output pin remains in a high-impedance state when chip enable is HIGH, or write enable (\overline{WE}) is LOW.

Capacitance^[5]

Parameters	Description	Test Conditions	Max.	Units
C _{IN}	Input Capacitance	T _A = 25°C, f = 1 MHz, V _{CC} = 5.0V	8	pF
C _{OUT}	Output Capacitance		8	pF

Notes:

1. T_A is the "instant on" case temperature.
2. See the last page of this specification for Group A subgroup testing information.
3. Duration of the short circuit should not exceed 30 seconds.
4. A pull-up resistor to V_{CC} on the \overline{CE} input is required to keep the device deselected during V_{CC} power-up, otherwise I_{SB} will exceed values given.
5. Tested initially and after any design or process changes that may affect these parameters.

t_{HZWE}	\overline{WE} LOW to High Z ^[7,8]		15		20		25	ns

Notes:

- Test conditions assume signal transition times of 5 ns or less, timing reference levels of 1.5V, input pulse levels of 0 to 3.0V, and output loading of the specified I_{OH1}/I_{OH} and 30-pF load capacitance.
- At any given temperature and voltage condition, t_{LZ} is less than t_{LZ} for all devices.
- t_{HZCE} and t_{HZWE} are tested with $C_L = 5\text{ pF}$ as in part (b) of AC Test Loads. Transition is measured $\pm 500\text{ mV}$ from steady state voltage.
- The internal write time of the memory is defined by the overlap of \overline{CE} LOW and \overline{WE} LOW. Both signals must be LOW to initiate a write and either signal can terminate a write by going HIGH. The data input set-up and hold timing should be referenced to the rising edge of the signal that terminates the write.
