

## Quad Differential Receivers BRF1A, BRF2A, BRS2B, BRR1A, and BRT1A

---

### Features

- Pin equivalent to the general-trade 26LS32 device, with improved speed, reduced power consumption, and significantly lower levels of EMI
- High input impedance approximately 8 k $\Omega$
- Four line receivers per package
- 400 Mbits/s maximum data rate when used with Agere Systems Inc. data transmission drivers
- Meets enhanced small device interface (ESDI) standards
- 4.0 ns maximum propagation delay
- <0.20 V input sensitivity
- -1.2 V to +7.2 V common-mode range
- -40 °C to +125 °C ambient operating temperature range (wider than the 41 Series)
- Single 5.0 V  $\pm$  10% supply
- Output defaults to logic 1 when inputs are left open\*
- Available in four package types
- Lower power requirement than the 41 Series

### Description

These quad differential receivers accept digital data over balanced transmission lines. They translate differential input logic levels to TTL output logic levels. All devices in this family have four receivers with a common enable control. These receivers are pin equivalent to the general-trade 26LS32, but offer increased speed and decreased power consumption. They replace the Agere 41 Series receivers.

\* This feature is available on BRF1A and BRF2A.

The BRF1A device is the generic receiver in this family and requires the user to supply external resistors on the circuit board for impedance matching.

The BRF2A is identical to the BRF1A, but has an electrostatic discharge (ESD) protection circuit added to significantly improve the ESD human-body model (HBM) characteristics on the differential input terminals.

The BRS2B is identical to the BRF2A, but has a preferred state feature that places the output in the high state when the inputs are open, shorted to ground, or shorted to the power supply.

The BRR1A is equivalent to the BRF1A, but has a 110  $\Omega$  resistor connected across the differential inputs. This eliminates the need for an external resistor when terminating a 100  $\Omega$  impedance line. This device is designed to work with the DP1A or PNPA in point-to-point applications.

The BRT1A is equivalent to the BRF1A; however, it is provided with a Y-type resistor network across the differential inputs and terminated to ground. The Y-type termination provides the best EMI results. This device is not recommended for applications where the differences in ground voltage between the driver and the receiver exceed 1 V. This device is designed to work with the DG1A or PNGA in point-to-point applications.

The powerdown loading characteristics of the receiver input circuit are approximately 8 k $\Omega$  relative to the power supplies; hence, they will not load the transmission line when the circuit is powered down. For those circuits with termination resistors, the line will remain impedance matched when the circuit is powered down.

The packaging options that are available for these quad differential line drivers include a 16-pin DIP; a 16-pin, J-lead SOJ; a 16-pin, gull-wing small-outline integrated circuit (SOIC); and a 16-pin, narrow-body, gull-wing SOIC.

## Electrical Characteristics (continued)

**Table 3. Voltage and Current Characteristics**

For variation in minimum  $V_{OH}$  and maximum  $V_{OL}$  over the temperature range, see Figure 8.  $T_A = -40\text{ }^\circ\text{C}$  to  $+125\text{ }^\circ\text{C}$ .

Parameter	Sym	Min	Typ	Max	Unit
Output Voltages, $V_{CC} = 4.5\text{ V}$ :					
Low, $I_{OL} = 8.0\text{ mA}$	$V_{OL}$	—	—	0.5	V
High, $I_{OH} = -400\text{ }\mu\text{A}$	$V_{OH}$	2.4	—	—	V
Enable Input Voltages:					
Low, $V_{CC} = 5.5\text{ V}$	$V_{IL}^1$	—	—	0.7	V
High, $V_{CC} = 5.5\text{ V}$	$V_{IH}^1$	2.0	—	—	V
Clamp, $V_{CC} = 4.5\text{ V}$ , $I_I = -5.0\text{ mA}$	$V_{IK}$	—	—	-1.0	V
Differential Input Voltages, $V_{IH} - V_{IL}$ : <sup>2</sup> $-0.80\text{ V} < V_{IH} < 7.2\text{ V}$ , $-1.2\text{ V} < V_{IL} < 6.8\text{ V}$	$V_{TH}^1$	—	0.1	0.20	V
Input Offset Voltage	$V_{OFF}$	—	0.02	0.05	V
Input Offset Voltage BRS2B	$V_{OFF}$	—	0.1	0.15	V
Output Currents, $V_{CC} = 5.5\text{ V}$ :					
Off-state (high Z), $V_o = 0.4\text{ V}$	$I_{OZL}$	—	—	-20	$\mu\text{A}$
Off-state (high Z), $V_o = 2.4\text{ V}$	$I_{OZH}$	—	—	20	$\mu\text{A}$
Short Circuit	$I_{OS}^3$	-25	—	-100	mA
Enable Currents, $V_{CC} = 5.5\text{ V}$ :					
Low, $V_{IN} = 0.4\text{ V}$	$I_{IL}$	—	—	-400	$\mu\text{A}$
High, $V_{IN} = 2.7\text{ V}$	$I_{IH}$	—	—	20	$\mu\text{A}$
Reverse, $V_{IN} = 5.5\text{ V}$	$I_{IH}$	—	—	100	$\mu\text{A}$
Differential Input Currents, $V_{CC} = 5.5\text{ V}$ :					
Low, $V_{IN} = -1.2\text{ V}$	$I_{IL}$	—	—	-1.0	mA
High, $V_{IN} = 7.2\text{ V}$	$I_{IH}$	—	—	1.0	mA
Differential Input Impedance (BRR1A): Connected Between $R_I$ and $\overline{R_I}$	$R_O$	—	110	—	$\Omega$
Differential Input Impedance (BRT1A) <sup>4</sup>	$R_1$ $R_2$	— —	60 90	— —	$\Omega$ $\Omega$

1. The input levels and difference voltage provide zero noise immunity and should be tested only in a static, noise-free environment.
2. Outputs of unused receivers assume a logic 1 level when the inputs are left open. (It is recommended that all unused positive inputs be tied to the positive power supply. No external series resistor is required.)
3. Test must be performed one lead at a time to prevent damage to the device.
4. See Figure 2.

**Figure 2. BRT1A Terminating Resistor Configuration**

## Timing Characteristics

**Table 4. Timing Characteristics** (See Figure 4 and Figure 5.)

For propagation delays ( $t_{PLH}$  and  $t_{PHL}$ ) over the temperature range, see Figure 9 and Figure 10.

Propagation delay test circuit connected to output is shown in Figure 6.

$T_A = -40\text{ }^\circ\text{C}$  to  $+125\text{ }^\circ\text{C}$ ,  $V_{CC} = 5\text{ V} \pm 0.5\text{ V}$ .

Parameter	Symbol	Min	Typ	Max	Unit
Propagation Delay:					
Input to Output High	$t_{PLH}$	1.5	2.5	4.0	ns
Input to Output Low	$t_{PHL}$	1.5	2.5	4.0	ns
Disable Time, $C_L = 5\text{ pF}$ :					
High-to-high Impedance	$t_{PHZ}$	—	5	12	ns
Low-to-high Impedance	$t_{PLZ}$	—	5	12	ns
Pulse Width Distortion, $t_{pHL} - t_{pLH}$ :					
Load Capacitance ( $C_L$ ) = 15 pF	$t_{skew1}$	—	—	0.7	ns
Load Capacitance ( $C_L$ ) = 150 pF	$t_{skew1}$	—	—	4.0	ns
Output Waveform Skews:					
Part-to-Part Skew, $T_A = 75\text{ }^\circ\text{C}$	$\Delta t_{skew1p-p}$	—	0.8	1.4	ns
Part-to-Part Skew, $T_A = -40\text{ }^\circ\text{C}$ to $+125\text{ }^\circ\text{C}$	$\Delta t_{skew1p-p}$	—	—	1.5	ns
Same Part Skew	$\Delta t_{skew}$	—	—	0.3	ns
Enable Time:					
High Impedance to High	$t_{PZH}$	—	8	12	ns
High Impedance to Low	$t_{PZL}$	—	8	12	ns
Rise Time (20%—80%)	$t_{rLH}$	—	—	3.0	ns
Fall Time (80%—20%)	$t_{fHL}$	—	—	3.0	ns

12-3462(F)

Note: This graph is included as an aid to the system designers. Total circuit delay varies with load capacitance. The total delay is the sum of the delay due to the external capacitance and the intrinsic delay of the device.

## Handling Precautions

**CAUTION:** This device is susceptible to damage as a result of ESD. Take proper precautions during both handling and testing. Follow guidelines such as JEDEC Publication No. 108-A (Dec. 1988).

When handling and mounting line driver products, proper precautions should be taken to avoid exposure to ESD. The user should adhere to the following basic rules for ESD control:

1. Assume that all electronic components are sensitive to ESD damage.
2. Never touch a sensitive component unless properly grounded.
3. Never transport, store, or handle sensitive components except in a static-safe environment.

## ESD Failure Models

Agere employs two models for ESD events that can cause device damage or failure:

1. An HBM that is used by most of the industry for ESD-susceptibility testing and protection-design evaluation. ESD voltage thresholds are dependent on the critical parameters used to define the model. A standard HBM (resistance = 1500  $\Omega$ , capacitance = 100 pF) is widely used and, therefore, can be used for comparison purposes.
2. A charged-device model (CDM), which many believe is the better simulator of electronics manufacturing exposure.

Table 5 and Table 6 illustrates the role these two models play in the overall prevention of ESD damage. HBM ESD testing is intended to simulate an ESD event from a charged person. The CDM ESD testing simulates charging and discharging events that occur in production equipment and processes, e.g., an integrated circuit sliding down a shipping tube.

The HBM ESD threshold voltage presented here was obtained by using the following circuit parameters:

**Table 5. Typical ESD Thresholds for Data Transmission Receivers**

Device	HBM Threshold		CDM Threshold
	Differential Inputs	Others	
BRF1A, BRR1A, BRT1A	>800	>2000	>1000
BRF2A, BRS2B	>2000	>2000	>2000

**Table 6. ESD Damage Protection**

	ESD Threat Controls	
	Personnel	Processes
<b>Control</b>	Wrist straps. ESD shoes. Antistatic flooring.	Static-dissipative materials. Air ionization.
<b>Model</b>	Human body model (HBM).	Charged-device model (CDM).

## Latch Up

Latch-up evaluation has been performed on the data transmission receivers. Latch-up testing determines if power-supply current exceeds the specified maximum due to the application of a stress to the device under test. A device is considered susceptible to latch up if the power supply current exceeds the maximum level and remains at that level after the stress is removed.

Agere performs latch up testing per an internal test method that is consistent with JEDEC Standard No. 17 (previously JC-40.2) *CMOS Latch Up Standardized Test Procedure*.

Latch up evaluation involves three separate stresses to evaluate latch up susceptibility levels:

1. dc current stressing of input and output pins.
2. Power supply slew rate.
3. Power supply overvoltage.

**Table 7. Latch Up Test Criteria and Test Results**

Data Transmission Receiver ICs	Minimum Criteria	dc Current Stress of I/O Pins	Power Supply Slew Rate	Power Supply Overvoltage
		Test Results	$\geq 150$ mA	$\leq 1$ $\mu$ s
		$\geq 250$ mA	$\leq 100$ ns	$\geq 2.25 \times V_{max}$

Based on the results in Table 7, the data transmission receivers pass the Agere latch-up testing requirements and are considered not susceptible to latch up.

## Power Dissipation

System designers incorporating Agere data transmission drivers in their applications should be aware of package and thermal information associated with these components.

Proper thermal management is essential to the long-term reliability of any plastic encapsulated integrated circuit. Thermal management is especially important for surface-mount devices, given the increasing circuit pack density and resulting higher thermal density. A key aspect of thermal management involves the junction temperature (silicon temperature) of the integrated circuit.

Several factors contribute to the resulting junction temperature of an integrated circuit:

- Ambient use temperature
- Device power dissipation
- Component placement on the board
- Thermal properties of the board
- Thermal impedance of the package

Thermal impedance of the package is referred to as  $\Theta_{ja}$  and is measured in °C rise in junction temperature per watt of power dissipation. Thermal impedance is also a function of airflow present in system application.

The following equation can be used to estimate the junction temperature of any device:

$$T_j = T_A + P_D \Theta_{ja}$$

where:

$T_j$  is device junction temperature (°C).

$T_A$  is ambient temperature (°C).

$P_D$  is power dissipation (W).

$\Theta_{ja}$  is package thermal impedance (junction to ambient—°C/W).

The power dissipation estimate is derived from two factors:

- Internal device power
- Power associated with output terminations

Multiplying  $I_{cc}$  times  $V_{CC}$  provides an estimate of internal power dissipation.

The power dissipated in the output is a function of the:

- Termination scheme on the outputs
- Termination resistors
- Duty cycle of the output

Package thermal impedance depends on:

- Airflow
- Package type (e.g., DIP, SOIC, SOIC/NB)

The junction temperature can be calculated using the previous equation, after power dissipation levels and package thermal impedances are known.

Figure 11 illustrates the thermal impedance estimates for the various package types as a function of airflow. This figure shows that package thermal impedance is higher for the narrow-body SOIC package. Particular attention should, therefore, be paid to the thermal management issues when using this package type.

In general, system designers should attempt to maintain junction temperature below 125 °C. The following factors should be used to determine if specific data transmission drivers in particular package types meet the system reliability objectives:

- System ambient temperature
- Power dissipation
- Package type
- Airflow
