## Two-Output PTIC Control IC

### Introduction

TCC-202 is a two-output high-voltage digital to analog control IC specifically designed to control and bias ON Semiconductor's Passive Tunable Integrated Circuits (PTICs).

These tunable capacitor control circuits are intended for use in mobile phones and dedicated RF tuning applications. The implementation of ON Semiconductor's tunable circuits in mobile phones enables significant improvement in terms of antenna radiated performance.

The tunable capacitors are controlled through a bias voltage ranging from 1 V to 24 V. The TCC-202 high-voltage PTIC control IC has been specifically designed to cover this need, providing two independent high-voltage outputs that control up to two different tunable PTICs in parallel. The device is fully controlled through a MIPI interface.

### Key Features

- Controls ON Semiconductor's PTIC Tunable Capacitors
- Compliant with Timing Needs of Cellular and Other Wireless System Requirements
- Integrated Boost Converter with 2 Programmable DAC Outputs (up to 24 V)
- Low Power Consumption
- MIPI-RFFE Interface
- Compliant with MIPI 26 MHz Read-back
- Available in WLCSP (RDL ball arrays)
- This is a Pb-Free Device

### Typical Applications

- Multi-band, Multi-standard, Advanced and Simple Mobile Phones
- Tunable Antenna Matching Networks
- Compatible with Closed-loop and Open-loop Antenna Tuner Applications

$V_{RIPPLE}$	Output ripple with all outputs at steady state	–	–	40	mV RMS	Over 2 V – 24 V for VHV = 23.5 V

THEORY OF OPERATION

Overview

The control IC outputs are directly controlled by programming the two DACs (DAC A and DAC B) through the digital interface.

The DAC stages are driven from a reference voltage, generating an analog output voltage driving a high-voltage amplifier supplied from the boost converter (see Figure 1 – Control IC Functional Block Diagram).

The control IC output voltages are scaled from 0 V to 24 V, with 128 steps of 188 mV ( $2 \times (24 / 255 \text{ V}) = 0.188235 \text{ V}$ ). The nominal control IC output can be approximated to  $188 \text{ mV} \times \text{DAC value}$ .

For performance optimization the boost output voltage (VHV) can be programmed to levels between 13 V and 28 V via the DAC\_boost register (4 bits with 1 V steps). The startup default level for the boosted voltage is  $VHV = 24 \text{ V}$ .

For proper operation and to avoid saturation of the output devices and noise issues it is recommended to operate the boosted VHV voltage at least 2 V above the highest programmed  $V_{OUT}$  voltage of any of the two outputs.

Operating Modes

The following operating modes are available:

1. **Shutdown Mode:** All circuit blocks are off, the DAC outputs are disabled and placed in high Z state and current consumption is limited to minimal leakage current. The shutdown mode is entered upon initial application of AVDD or upon VIO being placed in the low state. The contents of the registers are not maintained in shutdown mode.
2. **Startup Mode:** Startup is only a transitory mode. Startup mode is entered upon a VIO high state. In

startup mode all registers are reset to their default states, the digital interface is functional, the boost converter is activated, outputs OUT A and OUT B are disabled and the DAC outputs are placed in a high Z state. Control software can request a full hardware and register reset of the TCC-202 by sending an appropriate PWR\_MODE command to direct the chip from either the active mode or the low power mode to the startup mode. From the startup mode the device automatically proceeds to the active mode.

3. **Active Mode:** All blocks of the TCC-202 are activated and the DAC outputs are fully controlled through the digital interface, DACs remain off until enabled. The DAC settings can be dynamically modified and the HV outputs will be adjusted according to the specified timing diagrams. Each DAC can be individually controlled and/or switched off according to application requirements. Active mode is automatically entered from the startup mode. Active mode can also be entered from the low power mode under control software command.
4. **Low Power Mode:** In low power mode the serial interface stays enabled, the DAC outputs are disabled and are placed in a high Z state and the boost voltage circuit is disabled. Control software can request to enter the low power mode from the active mode by sending an appropriate PWR\_MODE command. The contents of all registers are maintained in the low power mode.

Figure 3. Modes of Operation

## TCC-202

### AVDD Power-On Reset (POR)

Upon application of AVDD the TCC-202 will be in shutdown mode. All circuit blocks are off and the chip draws only minimal leakage current.

### VIO Power-On Reset and Startup Conditions

A high level on VIO places the chip in startup mode which provides a POR to the TCC-202. POR resets all registers to their default settings as described in Table 8. VIO POR also resets the serial interface circuitry. POR is not a brown-out detector and VIO needs to be brought back to a low level to enable the POR to trigger again.

**Table 7. VIO POWER-ON RESET AND STARTUP**

Register	Default State for VIO POR	Comment
DAC Boost	[1011]	VHV = 24 V
Power Mode	[01]>[00]	Transitions from shutdown to startup and then automatically to active mode
DAC Enable	[000000]	V <sub>OUT</sub> A, B Disabled
DAC A		Output in High-Z Mode
DAC B		Output in High-Z Mode

### VIO Shutdown

A low level at any time on VIO places the chip in shutdown mode in which all circuit blocks are off. The contents of the registers are not maintained in shutdown mode.

**Table 8. VIO THRESHOLDS** (AVDD from 2.3 V to 5.5 V; T<sub>A</sub> = -30 to +85°C unless otherwise specified)

Parameter	Description	Min	Typ	Max	Unit	Comments
VIORST	VIO Low Threshold	-	-	0.2	V	When VIO is lowered below this threshold level the chip is reset and placed into the shutdown state

### Power Supply Sequencing

The AVDD input is typically directly supplied from the battery and thus is the first on. After AVDD is applied and before VIO is applied to the chip, all circuits are in the shutdown state and draw minimum leakage currents. Upon application of VIO, the chip automatically starts up using default settings and is placed in the active state waiting for a command via the serial interface.

**Table 9. TIMING** (AVDD from 2.3 V to 5.5 V; VIO from 1.62 V to 1.98 V; T<sub>A</sub> = -30 to +85°C; OUT A and OUT B; CHV = 47 nF; L<sub>BOOST</sub> = 15 μH; VHV = 24 V; Turbo-Charge mode off unless otherwise specified; VDDA = 1.7 V)

# TCC-202

**Figure 4. Output Settling Diagram**

**Figure 5. Startup Timing Diagram**

**Boost Control**

The TCC-202 integrates an asynchronous current control boost converter. It operates in a discontinuous mode and features spread-spectrum circuitry for Electro-Magnetic Interference (EMI) reduction. The average boost clock is 2 MHz and the clock is spread between 0.8 MHz and 4 MHz.

**Boost Output Voltage (VHV) Control Principle**

The asynchronous control starts the boost converter as soon as the VHV voltage drops below the reference set by the 4-bit DAC and stops the boost converter when the VHV voltage rises above the reference again.

Due to the slow response time of the control loop, the VHV voltage may drop below the set voltage before the control loop compensates for it. In the same manner, VHV can rise higher than the set value. This effect may reduce the maximum output voltage available. Please refer to Figure 7 below.

The asynchronous control reduces switching losses and improves the output (VHV) regulation of the DC/DC converter under light load, particularly in the situation where the TCC-202 only maintains the output voltages to fixed values.

Figure 6. VHV Voltage Waveform

**High Impedance (High Z) Feature**

In shutdown mode the OUT pins are set to a high impedance mode (high Z). Following is the principle of operation for the control IC:

1. The DAC output voltage  $V_{OUT}$  is defined by:

$$V_{OUT} = \frac{\text{DAC code}}{255} \times 24 \text{ V} \times 2 \quad (\text{eq. 1})$$

2. The voltage VHV defines the maximum supply voltage of the DAC supply output regulator and is set by a 4-bit control.
3. The maximum DAC DC output voltage  $V_{OUT}$  is limited to  $(VHV - 2 \text{ V})$ .
4. The minimum output DAC voltage  $V_{OUT}$  is 1.0 V max.

Figure 8. DAC Output Range Example B

Figure 7. DAC Output Range Example A

**Digital Interface**

The control IC is fully controlled through a MIPI RFFE-compliant digital interface. The digital interface is described in the following sections of this document, for detailed programming instructions please refer to the programming guide, available by contacting ON Semiconductor.

**Turbo-Charge Mode**

The TCC-202 control IC has a Turbo-Charge mode that significantly shortens the system settling time when changing programming voltages. In Turbo-Charge mode the DAC output target voltage is temporarily set to either a delta voltage above or a delta voltage below the actual desired target for the TCDLY time. It is recommended that  $V_{HV}$  be set to 24 V when using Turbo-Charge mode.

**Glide Mode**

Unlike turbo mode, which is intended to reduce the charging time, the glide mode extends the transition time of each DAC output. Each DAC has an individual control for turbo mode, glide mode or regular voltage switching. The glide mode can be enabled for a particular DAC through the INDEX register, by setting DAC State to '1' when glide mode is enabled, turbo mode is off for a particular DAC, but one DAC can be gliding while the other is turbo.

During glide mode the output voltage of a DAC is either increased or decreased to its set end point, in max 255 steps, where each DAC time step can be programmed between 2  $\mu$ s to 64  $\mu$ s. For programming the glide mode refer to the application note (coming soon). A programming input is not required to maintain a glide transition, all step controls are maintained by the part. Only the inputs to define the glide need to be programmed.

**RF Front-End Control Interface (MIPI RFFE Interface)**

The TCC-202 is a read/write slave device which is fully compliant to the MIPI Alliance Specification for RF Front-End Control Interface (RFFE) Version 1.10.00 26 July 2011. This device is rated at full-speed operation for  $1.62\text{ V} < V_{IO} < 1.98\text{ V}$ .

11	1

Step [us]	DAC state	0	1	2	3	4	5	6	7	8	9	10	11
9	TCDLY	Turbo OFF		18	27	36	45	54	63	72	81	90	99
7	TCDLY	Turbo OFF		14	21	28	35	42	49	56	63	70	77
5 (default)	TCDLY	Turbo OFF		10	15	20	25	30	35	40	45	50	55
3	TCDLY	Turbo OFF		6	9	12	15	18	21	24	27	30	33

The value of Turbo time is deducted based on the hardware comparison of new DAC value in respect to old DAC value, as follows:

If DAC new > DAC old, then  $T_{UP} = TCDLY$

If DAC new < DAC old, and DAC\_new\_divby2 < 21, then  $T_{DOWN} = TCDLY + TCM * (21 - DAC\_new\_divby2)$  If DAC new < DAC old, and DAC\_new\_divby2 > 21, then  $T_{DOWN} = TCDLY$

If DAC new < DAC old, and DAC\_new\_divby2 = 21, then  $T_{DOWN} = TCDLY$

<b>Register RFFE:</b>	<b>RFFE_REG_0x9</b>	<b>Address RFFE A[4:0]:</b>	<b>0x09</b>

Bits		Reserved			DAC_WAKEUP_CTRL	Turbo Latency Select	Reserved	Reserved
Reset	U-0	U-0	U-0	U-0	W-0	W-0	W-0	W-0

Bit [3]: DAC Wake-up Control applicable to Wake-up from LP

0 : (default) Don't apply Turbo when Wake-up from LP STD or LP FTA

1: Always apply Turbo UP when Wake-up from LP STD or LP FTA. Turbo UP is calculated based on DAC value prior to enter LP STD or LP FTA mode.

NOTE 1: Turbo is NOT applied after Wake-up to the DACs which are programmed with 0x00 in the DAC value register

NOTE 2: Turbo is NOT applied after Wake-up from FTA mode if a trigger (Turbo, Normal, Glide) was generated while TC2x2 was in LP FTA mode

NOTE 3: When Bit[3] = '1', then Turbo is applied after Wake-up regardless if:

- DAC values are updated or not
- last DAC value update is equal with old DAC value

NOTE 4: When RFFE\_REG\_0x31 / Wake-up DAC Ctrl is '0' (default) Turbo after Wake-Up is applied after first vlv\_too\_lowfalling edge is detected. When RFFE\_REG\_0x31 / Wake-up DAC Ctrl is '1' Turbo after Wake-up is applied after rc\_clk starts.

Bit [2]: Turbo UP latency Select when Wake-up from LP.

This field has no effect when DAC\_WAKEUP\_CTRL[1:0] = '00'

0: (default) Turbo UP latency is 50 μs

1: Turbo UP latency is 100 μs

Bits	SWR	CFPE	CLE	AFPE	DFPE	RURE	WURE	BGE
Reset	W-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0

RFFE\_STATUS register can be read any time after power-up without the need to enable the Read Operation as described below.

SWR Soft-Reset MIPI-RFFE registers

Write '1' to this bit to reset all the MIPI-RFFE registers, except RFFE\_REG\_0x1C, RFFE\_USID, and RFFE\_GROUP\_SID. This bit will always Read-back '0'.

The soft reset occurs in the last clock cycle of the MIPI-RFFE frame which Writes '1' to this bit.

Right immediately after this frame, all the MIPI-RFFE registers have the reset value and are ready to be reprogrammed as desired.

The OTP duplicated registers are reset to the values written in OTP.

SWR can be written only by USID messages. GSID and Broadcast frames will be ignored when writing to this register field. RFFE\_STATUS Bits [6:0] are set '1' by hardware to flag when a certain condition is detected, as described below. RFFE\_STATUS Bits [6:0] cannot be written, but it is cleared to '0' under following conditions:

- Hardware Self-reset is applied after RFFE\_STATUS is READ
- When SWR is written '1' with USID frames
- When power mode transitions through STARTUP mode '01'
- After Power-up Reset

**CFPE**

1: Command frame with parity error received.

On the occurrence of this error, the slave will ignore the entire Command Sequence

**CLE**

1: Incompatible command length, due to unexpected SSC received before command length to be completed.

On the occurrence of this error, the slave will accept Write data up to the last correct and complete frame. When MIPI-RFFE multi-byte Read command is detected, the slave will always replay with an extended Read command of length of one byte.

**AFPE**

1: Address frame with parity error received.

On the occurrence of this error, the slave will ignore the entire Command Sequence

**DFPE**

1: Data frame with parity error received.

On the occurrence of this error, the slave will ignore only the erroneous data byte (s)

**RURE**

1: Read of non-existent register was detected.

On the occurrence of this error, the slave will not respond to the Read command frame.

When the Read Operation is not enabled, any read from an address other than 0x1A, will set RURE and the slave will not respond to the Read command frame.

When the Read Operation is enabled, any read from an unoccupied RFFE register address will set RURE.

**WURE**

1: Write to non-existent register was detected.

On the occurrence of this error, the slave discards data being written, and on the next received frame, proceeds as normal

**BGE**

1: Read using the Broadcast ID was detected

On the occurrence of this error, the slave will ignore the entire Command Sequence

Reset	W-0	W-0	W-0	W-0	W-0	W-0	W-0	W-0

8. Trigger Mask bits [5:3] can be changed, either set or cleared, only with an individual message using USID

9. During broadcast MIPI-RFFE accesses using GSID = '0000', Trigger bits [2:0] are masked by the pre-existent setting of Trigger Mask Bits [5:3]

10. During Individual MIPI-RFFE accesses using USID, Trigger bits [2:0] are masked by the incoming Trigger Mask bits [5:3] within the same write message to RFFE\_REG\_0x1C register. During Individual MIPI-RFFE accesses using USID, pre-existent setting of Trigger Mask Bits [5:3] is ignored.

11. When RFFE\_REG\_0x1C/ Trigger\_Mask\_2 = '1' and Trigger\_Mask\_1 = '1' and Trigger\_Mask\_0 = '1', then DAC messages will be sent to DACs immediately after RFFE\_REG\_0x04 is received, without waiting for any trigger

12. Power mode field bits [7:6] and Triggers bits [2:0] can be changed by either MIPI-RFFE broadcast messages when USID field within the Register Write Command is 0x0, or individual messages when USID fields within the Register Write Command is equal with RFFE\_REG\_0x1F[3:0]

NOTE: All the 8 bits of RFFE\_REG\_0x1C register bits are NOT affected by SWR bit from RFFE\_STATUS register

Bit [7:6]: Power Mode

00: ACTIVE mode, defined by following hardware behavior:

- Boost Control active, VHV set by Digital Interface
- Vout A and B enabled and controlled by Digital Interface

01: STARTUP mode, defined by following hardware behavior: o

- Boost Control active, VHV set by Digital Interface
- Vout A and B disabled

10: LOW POWER mode is defined by following hardware behavior:

- Digital interface is active, while all other circuits are in lowpower mode

11: Reserved (State of hardware does not change)

Bit 5: Mask trigger 2

0: Trigger 2 not masked. Data goes to destination register after bit 2 is written value 1 (default)

1: Trigger 2 is masked. Data goes directly to the destination register

Bit 4: Mask trigger 1

0: Trigger 1 not masked. Data goes to destination register after bit 1 is written value 1 (default)

1: Trigger 1 is masked. Data goes directly to the destination register.

Bit 3: Mask trigger 0

0: Trigger 0 not masked. Data goes to destination register after bit 0 is written value 1 (default)

1: Trigger 0 is masked. Data goes directly to the destination register.

Bit 2: Trigger 2

Write 1 to this bit, to move data from shadowregisters into destination register. This trigger can be masked by bit 5.

Bit 1: Trigger 1

Write 1 to this bit, to move data from shadowregisters into destination register. This trigger can be masked by bit 4.

Bit 0: Trigger 0

Write 1 to this bit, to move data from shadowregisters into destination register. This trigger can be masked by bit 3.

Reset	0	0	0	1	W-0	W-1	W-1	W-1

USID = Unique Slave Identifier Register

1. USID field can be changed by:

- MIPI-RFFE broadcast messages when USID field within the Register Write Command is 0b0000
- MIPI-RFFE individual messages when USID field within the Register Write Command equal with content of RFFE\_REG\_0x1F[3:0]

2. In the sequence of writing USID field, the upper [7:4] must match the value 0b0001 hardcoded in the RFFE register 0x1F

NOTE: USID value is NOT retained during SHUTDOWN power mode.

NOTE: USID value is not affected by SWR bit from RFFE\_STATUS register.

# TCC-202

## Register 0 Write Command Sequence

The Command Sequence starts with an SSC which is followed by the Register 0 Write Command Frame. This Frame contains the Slave address, a logic one, and the seven bit word that will be written to Register 0. The Command Sequence is depicted below.

Figure 12. Register 0 Write Command Sequence

Table 13. RFFE COMMAND FRAME FOR REGISTER 0 WRITE COMMAND SEQUENCE

Description	SSC		Command Frame																
DAC Configuration	1	0	SA (3,0)							1	0	0	0	0	0	0	0	P	BP

## Register Write Command Sequence

The Write Register command sequence may be used to access each register (addresses 0–31).

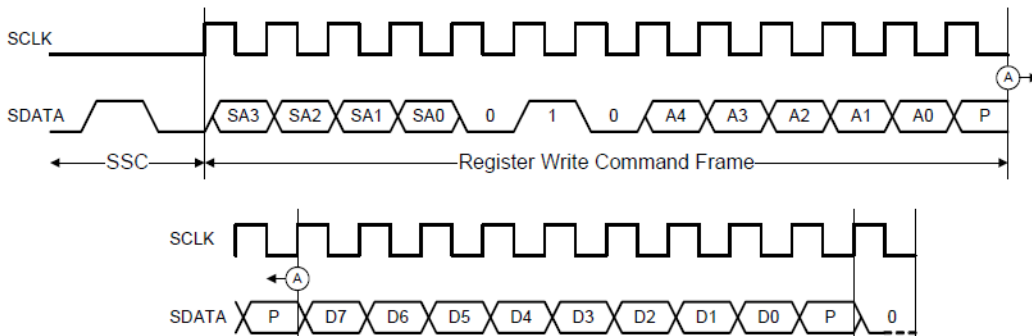

Figure 13. Register Write Command Sequence

Table 14. RFFE COMMAND FRAME FOR REGISTER WRITE COMMAND SEQUENCE for DACs Loading Procedure

Description	SSC		Command Frame											Data Frame		BP		
Turbo Charge Settings	1	0	SA (3,0)	0	1	0	0	0	0	0	0	0	1	P	Turbo charge (7:0)		P	BP
Register Write DAC A	1	0	SA (3,0)	0	1	0	0	0	0	0	1	0	P	DAC_A (6:0)		P	BP	
Register Write DAC B	1	0	SA (3:0)	0	1	0	0	0	0	0	1	1	P	DAC_B (6:0)		P	BP	

This sequence can be used for Read/Write procedure for some other purposes as shown on the following table:

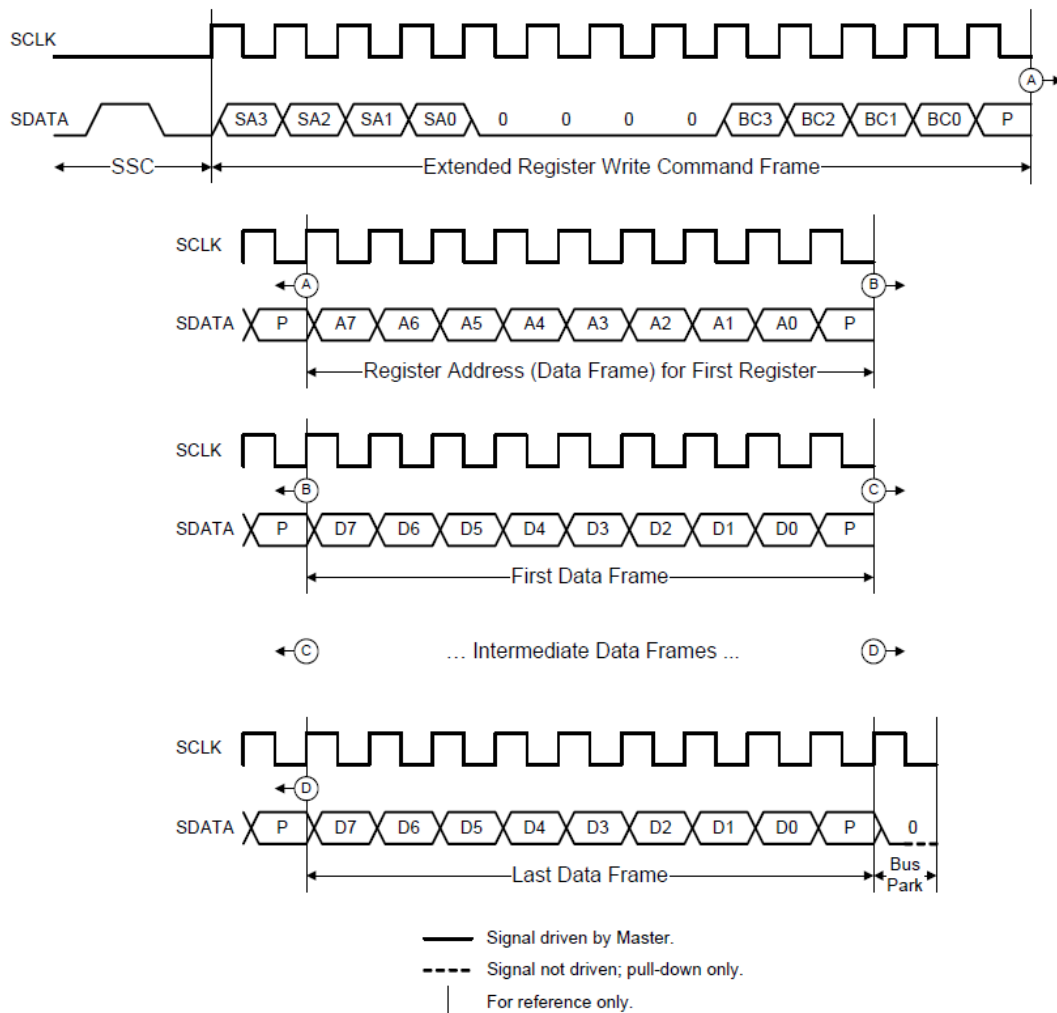

**Table 15. OTHER RFFE COMMAND SEQUENCES**

Description	SSC		Command Frame										Data Frame

Manufacturer USID	1	0	SA (3,0)	0	1	0	1	1	1	1	1	P	0	0	0	1	USID			BP	

**Extended Register Write Command Sequence**

In order to access more than one register in one sequence this message could be used. Most commonly it will be used for loading three DAC registers at the same time. The four LSBs of the Extended Register Write Command Frame determine the number of bytes that will be written by the Command Sequence. A value of 0b0000 would write one byte and a value of 0b1111 would write sixteen bytes.

If more than one byte is to be written, the register address in the Command Sequence contains the address of the first extended register that will be written to and the Slave’s local extended register address shall be automatically incremented by one for each byte written up to address 0x1F, starting from the address indicated in the Address Frame.

**Figure 14. Extended Register Write Command Sequence**
