Functional Description

The CY2PP3210 is a low-skew, low propagation delay dual 1-to-5 differential fanout buffer targeted to meet the requirements of high-performance clock and data distribution applications. The device is implemented on SiGe technology and has a fully differential internal architecture that is optimized to achieve low signal skews at operating frequencies of up to 1.5 GHz.

The device features two differential input paths that are differential internally. The CY2PP3210 may function not only as a differential clock buffer but also as a signal-level translator and fanout distributing a single-ended signal. An external bias pin, VBB, is provided for this purpose. In such an application, the VBB pin should be connected to either one of the CLKA# or CLKB# inputs and bypassed to ground via a 0.01- μ F capacitor. Traditionally, in ECL, it is used to provide the reference level to a receiving single-ended input that might have a differential bias point.

Since the CY2PP3210 introduces negligible jitter to the timing budget, it is the ideal choice for distributing high frequency, high precision clocks across back-planes and boards in communication systems. Furthermore, advanced circuit design schemes, such as internal temperature compensation, ensure that the CY2PP3210 delivers consistent performance over various platforms.

Notes:

1. In the I/O column, the following notation is used: I for Input, O for Output, PD for Pull-Down, PU for Pull-Up, and PWR for Power
2. In ECL mode (negative power supply mode), V_{EE} is either -3.3V or -2.5V and V_{CC} is connected to GND (0V). In PECL mode (positive power supply mode), V_{EE} is connected to GND (0V) and V_{CC} is either +3.3V or +2.5V. In both modes, the input and output levels are referenced to the most positive supply (V_{CC}) and are between V_{CC} and V_{EE} .
3. V_{BB} is available for use for single-ended bias mode for |3.3V| supplies (not |2.5V|).
