

### FEATURES

- Compresses/expands 64 kbps PCM voice to/from either 32 kbps, 24 kbps, or 16 kbps
- Dual, fully independent channel architecture; device can be programmed to perform either:
  - two expansions
  - two compressions
  - one expansion and one compression
- Interconnects directly to combo-codec devices
- Input to output delay is less than 375  $\mu$ s
- Simple serial port used to configure the device
- Onboard Time Slot Assigner Circuit (TSAC) function allows data to be input/output at various time slots
- Supports Channel Associated Signaling
- Each channel can be independently idled or placed into bypass
- Available hardware mode requires no host processor; ideal for voice storage applications
- Backward-compatible with the DS2167 ADPCM Processor Chip
- Single +5V supply; low-power CMOS technology
- Available in 24-pin DIP and 28-pin PLCC

### PIN ASSIGNMENT

24-PIN DIP (600-mil)

28-PIN PLCC

A 3-volt Operation Version  
is Available (DS2165QL)

### DESCRIPTION

The DS2165 ADPCM Processor Chip is a dedicated Digital Signal Processing (DSP) chip that has been optimized to perform Adaptive Differential Pulse Code Modulation (ADPCM) speech compression at three different rates. The chip can be programmed to compress (expand) 64 kbps voice data down to (up from) either 32 kbps, 24 kbps, or 16 kbps. The compression to 32 kbps follows the algorithm specified by CCITT Recommendation G.721 (July 1986) and ANSI document T1.301 (April 1987). The compression to 24 kbps follows ANSI document T1.303. The compression to 16 kbps follows a proprietary algorithm developed by Dallas Semiconductor. The DS2165 can switch compression algorithms on-the-fly. This allows the user to make maximum use of the available bandwidth on a dynamic basis.

## OVERVIEW

The DS2165 contains three major functional blocks: a high performance (10 MIPS) DSP engine, two independent PCM interfaces (X and Y) which connect directly to serial Time Division Multiplexed (TDM) backplanes, and a serial port that can configure the device on-the-fly via an external controller. A 10 MHz master clock is required by the DSP engine. The DS2165 can be configured to perform either two expansions, two compressions, or one expansion and one compression. The PCM/ADPCM data interfaces support data rates from 256 kHz to 4.096 MHz. Typically, the PCM data rates will be 1.544 MHz for  $\mu$ -law and 2.048 MHz for A-law. Each channel on the device samples the serial input PCM or ADPCM bit stream during a user-programmed input time slot, processes the data and outputs the result during a user-programmed output time slot.

Each PCM interface has a control register which specifies functional characteristics (compress, expand, bypass, and idle), data format ( $\mu$ -law or A-law), and algorithm reset control. With the SPS pin strapped high, the software mode is enabled and the serial port can be used to configure the device. In this mode, a novel addressing scheme allows multiple devices to share a common 3-wire control bus, simplifying system-level interconnect.

With SPS low, the hardware mode is enabled. This mode disables the serial port and maps certain control register bits to some of the address and serial port pins. Under the hardware mode, no external host controller is required and all PCM/ADPCM input and output time slots default to time slot 0.

## HARDWARE RESET

$\overline{\text{RST}}$  allows the user to reset both channel algorithms and the contents of the internal registers. This pin must be held low for at least 1 ms on system power-up after the master clock is stable to ensure that the device has initialized properly.  $\overline{\text{RST}}$  should also be asserted when changing to or from the hardware mode.  $\overline{\text{RST}}$  clears all bits of the Control Register for both channels except the IPD bits; the IPD bits for both channels are set to 1.

## SOFTWARE MODE

Tying SPS high enables the software mode. In this mode, an external host controller writes configuration data to the DS2165 via the serial port through inputs SCLK, SDI, and  $\overline{\text{CS}}$ . (See Figure 2.) Each write to the DS2165 is either a 2-byte write or a 4-byte write. A 2-byte write consists of the Address/Command Byte (ACB), followed by a byte to configure the Control Register (CR) for either the X or Y channel. The 4-byte write consists of the ACB, followed by a byte to configure the CR, and then 1 byte to set the input time slot and another byte to set the output time slot.

## ADDRESS/COMMAND BYTE

In the software mode, the address/command byte is the first byte written to the serial port; it identifies which of the 64 possible ADPCM processors sharing the port wiring is to be updated. Address data must match that at inputs A0 to A5. If no match occurs, the device ignores the following configuration data. If an address match occurs, the next 3 bytes written are accepted as control, input and output time slot data. Bit ACB.6 determines which side (X or Y) of the device is to be updated. The PCM and ADPCM outputs are tristated during register updates.

## CONTROL REGISTER

The control register establishes idle, algorithm reset, bypass, data format and channel coding for the selected channel.

The X and Y side PCM interfaces can be independently disabled (output 3-stated) via IPD. When IPD is set for both channels, the device enters a low-power standby mode. In this mode, the serial port must not be operated faster than 39 kHz.

ALRST resets the algorithm coefficients for the selected channel to their initial values. ALRST will be cleared by the device when the algorithm reset is complete.

**PIN DESCRIPTION Table 1**

PIN	SYMBOL	TYPE	DESCRIPTION
1	$\overline{\text{RST}}$	I	<b>Reset.</b> A high-low-high transition resets the algorithm. The device should be reset on power-up and when changing to or from the hardware mode.
2	TM0	I	<b>Test Modes 0 and 1.</b> Tie to $V_{SS}$ for normal operation.
3	TM1	I	
4	A0	I	<b>Address Select.</b> A0 = LSB; A5 = MSB; must match address/command word to enable the serial port.
5	A1		
6	A2		
7	A3		
8	A4		
9	A5		
10	SPS	I	<b>Serial Port Select.</b> Tie to $V_{DD}$ to select the serial port; tie to $V_{SS}$ to select the hardware mode.
11	MCLK	I	<b>Master Clock.</b> 10 MHz clock for the ADPCM processing engine; may be asynchronous to SCLK, CLKX, and CLKY.
12	$V_{SS}$	-	<b>Signal Ground.</b> 0.0 volts.
13	XIN	I	<b>X Data In.</b> Sampled on falling edge of CLKX during selected time slots.
14	CLKX	I	<b>X Data Clock.</b> Data clock for the X side PCM interface; must be synchronous with FSX.
15	FSX	I	<b>X Frame Sync.</b> 8 kHz frame sync for the X side PCM interface.
16	XOUT	O	<b>X Data Output.</b> Updated on rising edge of CLKX during selected time slots.
17	SCLK	I	<b>Serial Data Clock.</b> Used to write to the serial port registers.
18	SDI	I	<b>Serial Data In.</b> Data for onboard control registers; sampled on the rising edge of SCLK. LSB sent first.
19	$\overline{\text{CS}}$	I	<b>Chip Select.</b> Must be low to write to the serial port.
20	YOUT	O	<b>Y Data Output.</b> Updated on rising edge of CLKY during selected time slots.
21	FSY	I	<b>Y Frame Sync.</b> 8 kHz frame sync for the Y side PCM interface.
22	CLKY	I	<b>Y Data Clock.</b> Data clock for the Y side PCM interface; must be synchronous with FSY.
23	YIN	I	<b>Y Data In.</b> Sampled on falling edge of CLKY during selected time slots.
24	$V_{DD}$	-	<b>Positive Supply.</b> 5.0 volts (or 3.0 volts for DS2165QL).

## DS2165 BLOCK DIAGRAM Figure 1

## SERIAL PORT WRITE Figure 2

### NOTE:

1. A 2-byte write is shown.

The bypass feature is enabled when  $\overline{\text{BYP}}$  is set and  $\overline{\text{IPD}}$  is cleared. During bypass, no expansion or compression occurs. Bypass operates on byte-wide (8 bits) slots when  $\overline{\text{CP/EX}}$  is set and on nibble-wide (4 bits) slots when  $\overline{\text{CP/EX}}$  is cleared.

A-law ( $\overline{\text{U/A}} = 0$ ) and  $\mu$ -law ( $\overline{\text{U/A}} = 1$ ) PCM coding is independently selected for the X and Y channels via CR.2. If  $\overline{\text{BYP}}$  and  $\overline{\text{IPD}}$  are cleared, then  $\overline{\text{CP/EX}}$  determines if the input data is to be compressed or expanded.

## TIME SLOT ASSIGNMENT/ORGANIZATION

Onboard counters establish when PCM and ADPCM I/O occur. The counters are programmed via the time slot registers. Time slot size (number of bits wide) is determined by the state of  $\overline{CP/EX}$ . The number of time slots available is determined by the state of both  $\overline{CP/EX}$  and  $\overline{U/A}$ . (See Figures 7 through 10.) For example, if the X channel is set to compress ( $\overline{CP/EX} = 1$ ) and it is set to expect  $\mu$ -law data ( $\overline{U/A} = 1$ ), then the input port (XIN) is set up for 32 8-bit time slots and the output port (XOUT) is set up for 64 4-bit time slots. The time slot organization is not dependent on which algorithm has been selected. NOTE: Time slots are counted from the frame sync signal starting at the first rising edge of either CLKX or CLKY after the frame sync.

## HARDWARE MODE

The hardware mode is intended for applications that do not have an external controller available or do not require the extended features offered by the serial port. Tying the SPS pin to  $V_{SS}$  disables the serial port, clears all internal register bits and maps the IPD,  $U/\bar{A}$ , and  $CP/\bar{EX}$  bits for both channels to external bits. (See Table 3.) In the hardware mode, both the input and output time slots default to time slot 0.

**HARDWARE MODE Table 3**

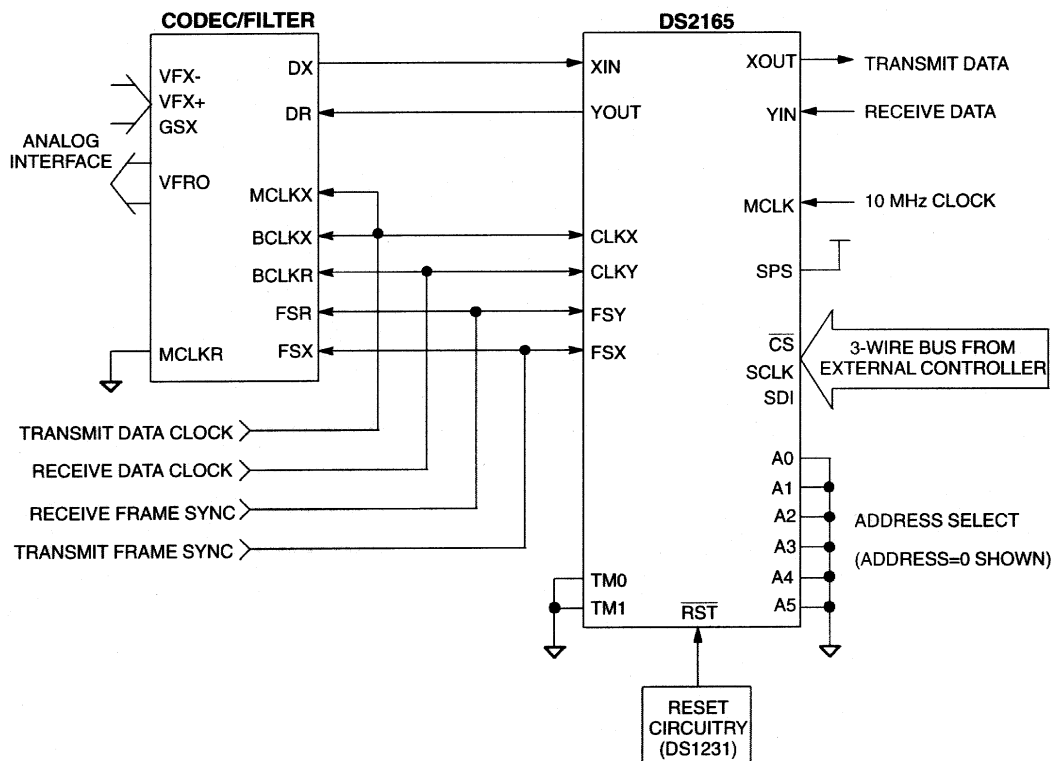

PIN # / NAME	REG. LOCATION	NAME AND DESCRIPTION
4 / A0	$CP/\bar{EX}$ (Channel X)	Channel X Coding Configuration 0 = Expand 1 = Compress
5 / A1	AS0/AS1/AS2 (Channel X & Y)	Algorithm Select (see Table 5)
6 / A2	$U/\bar{A}$ (Channel X)	Channel X Data Format 0 = A-law 1 = $\mu$ -law
7 / A3	$CP/\bar{EX}$ (Channel Y)	Channel Y Coding Configuration 0 = Expand 1 = Compress
8 / A4	AS0/AS1/AS2 (Channel X & Y)	Algorithm Select (see Table 5)
9 / A5	$U/\bar{A}$ (Channel Y)	Channel Y Data Format 0 = A-law 1 = $\mu$ -law
18 / SDI	IPD (Channel Y)	Channel Y Idle Select 0 = Channel active 1 = Channel idle
19 / $\bar{CS}$	IPD (Channel X)	Channel X Idle Select 0 = Channel active 1 = Channel idle

### NOTES:

1. SCLK must be tied to  $V_{SS}$  when the hardware mode is selected.
2. When both channels are idled, power consumption is significantly reduced.
3. The NIL will power-up within 800 ms after either channel is returned to active from an idle state.

**ALGORITHM SELECT FOR HARDWARE MODE Table 4**

ALGORITHM	CONFIGURATION OF A1 AND A4
64kbps to/from 32kbps	Tie both A1 and A4 to $V_{SS}$ .
64kbps to/from 24kbps	Hold A1 and A4 low during a hardware reset; take both A1 and A4 high after the $\overline{RST}$ pin has returned high (allow 3 $\mu s$ after $\overline{RST}$ returns high before taking A1 and A4 high).
64kbps to/from 16kbps	Tie both A1 and A4 to $V_{DD}$ .

**DS2165 CONNECTION TO CODEC/FILTER Figure 11****NOTE:**

MC1455XX	Motorola
TCM29CXX	Texas Instruments
HD44238C	Hitachi

\*other generic Codec/Filter devices can be substituted.

## PCM AND ADPCM INPUT/OUTPUT

Since the organization of the input and output time slots on the DS2165 does not depend on the algorithm selected, it always assumes that PCM input and output will be in 8-bit bytes and that ADPCM input and output will be in 4-bit bytes. Figure 12 demonstrates how the DS2165 handles the I/O for the three different algorithms. In the figure, it is assumed that channel X is in the compression mode ( $CP/\overline{EX} = 1$ ) and channel Y is in the expansion mode ( $CP/\overline{EX} = 0$ ). Also, it is assumed that both the input and output time slots for both channels are set to 0.

### PCM AND ADPCM I/O EXAMPLE Figure 12

#### NOTE:

1. The bit after the LSB in the 24kbps ADPCM output will only be a 1 when the DS2165 is operated in the software mode and is programmed to perform 24kbps compression; in all other configurations, it will be a 0.

---

## **TIME SLOT RESTRICTIONS**

Under certain conditions, the DS2165 does contain some restrictions on the output time slots that are available. These restrictions are covered in detail in a separate application note. No restrictions occur if the DS2165 is operated in the hardware mode.

## **INPUT TO OUTPUT DELAY**

With all three compressions algorithms, the total delay, from the time the PCM data sample is captured by the DS2165 to the time it is output, is always less than 375  $\mu$ s. The exact delay is determined by the input and output time slots selected for each channel.

## **CHANNEL ASSOCIATED SIGNALING**

The DS2165 supports Channel Associated Signaling (CAS) via its ability to automatically change from the 32 kbps compression algorithm to the 24 kbps algorithm. If the DS2165 is configured to perform the 32 kbps algorithm, then in both the hardware and software mode it will sense the frame sync inputs (FSX and FSY) for a double-wide frame sync pulse. Whenever the DS2165 receives a double-wide pulse, it will automatically switch from the 32kbps algorithm to the 24kbps algorithm. Switching to the 24kbps algorithm allows the user to insert signaling data into the LSB bit position of the ADPCM output because this bit does not contain any useful speech information.

## **ON-THE-FLY ALGORITHM SELECTION**

In the software mode, the user can switch between the three available algorithms on-the-fly. That is, the DS2165 does not need to be reset or stopped to make the change from one algorithm to another. The DS2165 reads the Control Register before it starts to process each PCM or ADPCM sample. If the user wishes to switch algorithms, then the Control Register must be updated via the serial port before the first input sample to be processed with the new algorithm arrives at either XIN or YIN. The PCM and ADPCM outputs will tristate during register updates.

**ABSOLUTE MAXIMUM RATINGS\***

Voltage on any Pin Relative to Ground	-1.0V to +7.0V
