## $512 \mathrm{~K} \times 36 / 1 \mathrm{M} \times 18$ Flow-Thru SRAM with NoBL $^{\text {TM }}$ Architecture

## Features

- Pin-compatible and functionally equivalent to $Z_{B T}{ }^{T M}$ devices
- Supports 117-MHz bus operations with zero wait states - Data is transferred on every clock
- Internally self-timed output buffer control to eliminate the need to use asynchronous OE
- Registered inputs for flow-thru operation
- Byte Write capability
- Common I/O architecture
- Fast clock-to-output times
-7.5 ns (for 117-MHz device)
- 8.5 ns (for $100-\mathrm{MHz}$ device)
- 10.0ns (for $83-\mathrm{MHz}$ device)
- Single $3.3 \mathrm{~V}-5 \%$ and $+10 \%$ power supply $V_{D D}$
- Separate $\mathrm{V}_{\mathrm{DDQ}}$ for 3.3 V or 2.5 V I/O
- Clock enable (CEN) pin to suspend operation
- Synchronous self-timed writes
- Available in 100 TQFP and 119 BGA packages
- Burst capability - linear or interleaved burst order
- JTAG boundary scan for BGA packaging version
- Automatic power down available using ZZ mode or CE deselect

## Functional Description

The CY7C1371B/CY7C1373B is 3.3V, 512K x 36 and $1 \mathrm{M} \times 18$ synchronous flow-thru burst SRAMs, respectively designed to support unlimited true back-to-back Read/Write operations without the insertion of wait states. The CY7C1371B/ CY7C1373B is equipped with the advanced No Bus Latency ${ }^{\text {™ }}$ (NoBL ${ }^{\text {M }}$ ) logic required to enable consecutive Read/Write operations with data being transferred on every clock cycle. This feature dramatically improves the throughput of data through the SRAM, especially in systems that require frequent Write/Read transitions.The CY7C1371B/CY7C1373B is pin compatible and functionally equivalent to ZBT devices.
All synchronous inputs pass through input registers controlled by the rising edge of the clock. The clock input is qualified by the Clock enable ( $\overline{\mathrm{CEN}}$ ) signal, which when deasserted suspends operation and extends the previous clock cycle. Maximum access delay from the clock rise is $7.5 \mathrm{~ns}(117-\mathrm{MHz}$ device).
Write operations are controlled by the byte Write Selects ( $\overline{\mathrm{BWS}}_{\mathrm{a}, \mathrm{b}, \mathrm{c}, \mathrm{d}}$ for CY7C1371B and $\overline{\mathrm{BWS}}_{\mathrm{a}, \mathrm{b}}$ for CY7C1373B) and a Write enable (WE) input. All writes are conducted with on-chip synchronous self-timed Write circuitry. ZZ may be tied to LOW if it is not used.
Synchronous Chip enables ( $\overline{\mathrm{CE}}_{1}, \mathrm{CE}_{2}, \overline{\mathrm{CE}}_{3}$ on the TQFP, $\overline{\mathrm{CE}}_{1}$ on the BGA) and an asynchronous Output enable (OE) provide for easy bank selection and output three-state control. In order to avoid bus contention, the output drivers are synchronously three-stated during the data portion of a Write sequence.

## Selection Guide

|  | $\mathbf{1 1 7} \mathbf{~ M H z}$ | $\mathbf{1 0 0} \mathbf{~ M H z}$ | $\mathbf{8 3} \mathbf{~ M H z}$ | Unit |

## Pin Definitions

| Name | I/O Type | Description |
| :---: | :---: | :---: |
| $\begin{aligned} & \hline \text { A0 } \\ & \text { A1 } \\ & \text { A } \end{aligned}$ | InputSynchronous | Address inputs used to select one of the 532,288/1,048,576 address locations. Sampled at the rising edge of the CLK. |
| $\overline{\mathrm{BWS}} \mathrm{a}$ BWSb BWSc BWSd | InputSynchronous | Byte Write Select inputs, active LOW. Qualified with $\overline{\text { WE }}$ to conduct Writes to the SRAM. Sampled on the rising edge of CLK. BWSa controls DQa and DPa, BWSb controls DQb and DPb, $\bar{B} W S c$ controls DQc and DPc, $\overline{B W S} d$ controls DQd and DPd. |
| $\overline{\text { WE }}$ | InputSynchronous | Write enable input, active LOW. Sampled on the rising edge of CLK if $\overline{\mathrm{CEN}}$ is active LOW. This signal must be asserted LOW to initiate a Write sequence. |
| ADV/ $\overline{\mathrm{LD}}$ | InputSynchronous | Advance/Load input used to advance the on-chip address counter or load a new address. When HIGH (and CEN is asserted LOW) the internal burst counter is advanced. When LOW, a new address can be loaded into the device for an access. After being deselected, ADV/LD should be driven LOW in order to load a new address. |
| CLK | Input-Clock | Clock input. Used to capture all synchronous inputs to the device. CLK is qualified with $\overline{\mathrm{CEN}}$. CLK is only recognized if CEN is active LOW. |
| $\overline{\mathrm{CE}}_{1}$ | InputSynchronous | Chip enable 1 input, active LOW. Sampled on the rising edge of CLK. Used in conjunction with $\mathrm{CE}_{2}$ and $\overline{\mathrm{CE}}_{3}$ to select/deselect the device. |
| $\mathrm{CE}_{2}$ | Input- <br> Synchronous | Chip enable 2 input, active HIGH. Sampled on the rising edge of CLK. Used in conjunction with $\overline{\mathrm{CE}}_{1}$ and $\overline{\mathrm{CE}}_{3}$ to select/deselect the device. |
| $\overline{\mathrm{CE}}_{3}$ | InputSynchronous | Chip enable 3 input, active LOW. Sampled on the rising edge of CLK. Used in conjunction with $\overline{\mathrm{CE}}_{1}$ and $\mathrm{CE}_{2}$ to select/deselect the device. |
| $\overline{\mathrm{OE}}$ | Input- <br> Asynchronous | Output enable, active LOW. Combined with the synchronous logic block inside the device to control the direction of the I/O pins. When LOW, the I/O pins are allowed to behave as outputs. When deasserted HIGH, I/O pins are three-stated, and act as input data pins. $\overline{\mathrm{OE}}$ is masked during the data portion of a Write sequence, during the first clock when emerging from a deselected state and when the device has been deselected. |
| $\overline{\mathrm{CEN}}$ | InputSynchronous | Clock enable input, active LOW. When asserted LOW the clock signal is recognized by the SRAM. When deasserted HIGH the clock signal is masked. Since deasserting CEN does not deselect the device, $\overline{C E N}$ can be used to extend the previous cycle when required. |
| DQa <br> DQb <br> DQc <br> DQd | I/O- <br> Synchronous | Bidirectional Data I/O lines. As inputs, they feed into an on-chip data register that is triggered by the rising edge of CLK. As outputs, they deliver the data contained in the memory location specified by $\mathrm{A}_{\left[\mathrm{xI}_{1}\right.}$ during the previous clock rise of the Read cycle. The direction of the pins is controlled by $\overline{O E}$ and the internal control logic. When OE is asserted LOW, the pins can behave as outputs. When HIGH, DQa - DQd are placed in a three-state condition. The outputs are automatically three-stated during the data portion of a Write sequence, during the first clock when emerging from a deselected state, and when the device is deselected, regardless of the state of $\overline{\mathrm{OE}}$. DQ a, b, c and d are eight-bits wide. |
| DPa <br> DPb <br> DPc <br> DPd | I/OSynchronous | Bidirectional Data Parity I/O lines. Functionally, these signals are identical to $D_{[31: 0]}$ : During Write sequences, DPa is controlled by BWSa, DPb is controlled by BWSb, DPc is controlled by BWSc, and DPd is controlled by BWSd. DP a, b, c and d are one-bit wide. |
| ZZ | InputAsynchronous | ZZ "sleep" input. This active HIGH input places the device in a non-time critical "sleep" condition with data integrity preserved. |
| MODE | Input Pin | Mode input. Selects the burst order of the device. Tied HIGH selects the interleaved burst order. Pulled LOW selects the linear burst order. MODE should not change states during operation. When left floating MODE will default HIGH, to an interleaved burst order. |
| $V_{\text {DD }}$ | Power Supply | Power supply inputs to the core of the device. |
| $\mathrm{V}_{\text {DDQ }}$ | I/O Power Supply | Power supply for the I/O circuitry. |
| $\mathrm{V}_{\text {SS }}$ | Ground | Ground for the device. Should be connected to ground of the system. |
| TDO | JTAG serial output Synchronous | Serial data-out to the JTAG circuit. Delivers data on the negative edge of TCK (BGA only). |
| TDI | JTAG serial input Synchronous | Serial data-In to the JTAG circuit. Sampled on the rising edge of TCK (BGA only). |

## Pin Definitions

| Name | I/O Type | Description |
| :--- | :--- | :--- |
| TMS | Test Mode Select <br> Synchronous | This pin controls the Test Access Port (TAP) state machine. Sampled on the rising edge <br> of TCK (BGA only) |
| TCK | JTAG serial <br> clock | Serial clock to the JTAG circuit (BGA only) |
| $32 M$ <br> $64 M$ <br> $128 M$ | - | No connects. Reserved for address expansion. Pins are not internally connected. |
| NC | - | No connects. Pins are not internally connected. |
| DNU | - | Do not use pins. |

## Functional Overview

The CY7C1371B/CY7C1373B is a synchronous flow-thru burst NoBL SRAM specifically designed to eliminate wait states during Write-Read transitions. All synchronous inputs pass through input registers controlled by the rising edge of the clock. The clock signal is qualified with the clock enable input signal (CEN). If CEN is HIGH, the clock signal is not recognized and all internal states are maintained. All synchronous operations are qualified with $\overline{\mathrm{CEN}}$. Maximum access delay from the clock rise ( $\mathrm{t}_{\mathrm{CDV}}$ ) is 7.5 ns ( $117-\mathrm{MHz}$ device).
Accesses can be initiated by asserting chip enable(s) ( $\overline{\mathrm{CE}}_{1}$, $\mathrm{CE}_{2}, \mathrm{CE}_{3}$ on the TQFP, $\mathrm{CE}_{1}$ on the BGA) active at the rising edge of the clock. If the clock enable (CEN) is active LOW and ADV/LD is asserted LOW, the address presented to the device will be latched. The access can be either a Read or Write operation, depending on the status of the Write enable (WE). Byte Write Selects can be used to conduct byte Write opera-

> tions.

Write operations are qualified by the $\overline{\mathrm{WE}}$. All Writes are simplified with on-chip, synchronous, self-timed Write circuitry. A synchronous chip enable ( $\overline{\mathrm{CE}}_{1}, \mathrm{CE}_{2}$, and $\overline{\mathrm{CE}}_{3}$ on the TQFP, $\overline{\mathrm{CE}}_{1}$ on the BGA ) and an asynchronous $\overline{\mathrm{OE}}$ simplify depth expansion. All operations (Reads, Writes, and Deselects) are pipelined. ADV/LD should be driven LOW once the device has been deselected in order to load a new address for the next operation.

## Single Read Access

A Read access is initiated when the following conditions are satisfied at clock rise: (1) CEN is asserted LOW , (2) $\mathrm{CE}_{1}, \mathrm{CE}_{2}$, and $\mathrm{CE}_{3}$ are ALL asserted active, (3) WE is deasserted HIGH, and 4) ADV/LD is asserted LOW. The address presented to the address inputs is latched into the Address register and presented to the memory core and control logic. The control logic determines that a Read access is in progress and allows the requested data to propagate to the output buffers. The data is available within 6.5 ns ( $133-\mathrm{MHz}$ device) provided $\overline{\mathrm{OE}}$ is active LOW. After the first clock of the Read access the output buffers are controlled by OE and the internal control logic. OE must be driven LOW in order for the device to drive out the requested data. On the subsequent clock, another operation (Read/Write/Deselect) can be initiated. When the SRAM is deselected at clock rise by one of the chip enable signals, its output will be three-stated immediately.

## Burst Read Access

The CY7C1371B/CY7C1373B has an on-chip burst counter that allows the user the ability to supply a single address and conduct up to four Reads without reasserting the address inputs. ADV/ $\overline{\mathrm{LD}}$ must be driven LOW in order to load a new address into the SRAM, as described in the Single Read Access section above. The sequence of the burst counter is determined by the MODE input signal. A LOW input on MODE selects a linear burst mode, a HIGH selects an interleaved burst sequence. Both burst counters use A0 and A1 in the burst sequence, and will wrap-around when incremented sufficiently. A HIGH input on ADV/LD will increment the internal burst counter regardless of the state of chip enables inputs or WE. WE is latched at the beginning of a burst cycle. Therefore, the type of access (Read or Write) is maintained throughout the burst sequence.

## Single Write Access

Write access is initiated when the following conditions are satisfied at clock rise: (1) CEN is asserted LOW, (2) chip enable(s) asserted active, and (3) $\overline{W E}$ is asserted LOW. The address presented is loaded into the Address register. The Write signals are latched into the Control Logic block. The data lines are automatically three-stated regardless of the state of the $\overline{\mathrm{OE}}$ input signal. This allows the external logic to present the data on DQ and DP.
On the next clock rise the data presented to DQ and DP (or a subset for byte Write operation) inputs is latched into the device and the Write is complete (see Write Cycle Description table for details). Additional accesses (Read/Write/Deselect) can be initiated on this cycle.
The data written during the Write operation is controlled by byte Write Select signals. The CY7C1371B/CY7C1373B provides byte Write capability that is described in the Write Cycle Description table. Asserting the WE input with the selected byte Write Select input will selectively write to only the desired bytes. Bytes not selected during a byte Write operation will remain unaltered. A synchronous self-timed Write mechanism has been provided to simplify the Write operations. Byte Write capability has been included in order to greatly simplify Read/Modify/Write sequences, which can be reduced to simple byte Write operations.
Because the CY7C1371B/CY7C1373B are common I/O devices, data should not be driven into the device while the outputs are active. The $\overline{\mathrm{OE}}$ can be deasserted HIGH before presenting data to the DQ and DP inputs. Doing so will three-state the output drivers. As a safety precaution, DQ and

DP are automatically three-stated during the data portion of a Write cycle, regardless of the state of $\overline{\mathrm{OE}}$.

## Burst Write Access

The CY7C1371B/CY7C1373B has an on-chip burst counter that allows the user the ability to supply a single address and conduct up to four Write operations without reasserting the address inputs. ADV/ $\overline{\mathrm{LD}}$ must be driven LOW in order to load
the initial address, as described in the Single Write Access section above. When ADV/LD is driven HIGH on the subsequent clock rise, the chip enables ( $\overline{\mathrm{CE}}_{1}, \mathrm{CE}_{2}$, and $\left.\overline{\mathrm{CE}}_{3}\right)$ and WE inputs are ignored and the burst counter is incremented. The correct $\overline{\mathrm{BWS}}_{\mathrm{a}, \mathrm{b}, \mathrm{c}, \mathrm{d}} / \overline{\mathrm{BWS}}_{\mathrm{a}, \mathrm{b}}$ inputs must be driven in each cycle of the burst Write in order to write the correct bytes of data.

Cycle Description Truth Table ${ }^{[1,2,3,4,5,6]}$

## ZZ-Mode Electrical Characteristics

| Parameter | Description | Test Conditions | Min. | Max. | Unit |
| :--- | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{I}_{\mathrm{DDZZ}}$ | Snooze mode standby current | $\mathrm{ZZ} \geq \mathrm{V}_{\mathrm{DD}}-0.2 \mathrm{~V}$ |  | 20 | mA |
| $\mathrm{t}_{\mathrm{ZZS}}$ | Device operation to ZZ | $\mathrm{ZZ} \geq \mathrm{V}_{\mathrm{DD}}-0.2 \mathrm{~V}$ |  | $2 \mathrm{t}_{\mathrm{CYC}}$ | ns |
| $\mathrm{t}_{\mathrm{ZZREC}}$ | ZZ recovery time | $\mathrm{ZZ} \leq 0.2 \mathrm{~V}$ | $2 \mathrm{t}_{\mathrm{CYC}}$ |  | ns |

## Notes:

1. $X=$ "Don't Care," $1=$ Logic HIGH, $0=$ Logic LOW, CE stands for ALL chip enables. CE $=0$ stands for ALL chip enables active.
2. Write is defined by $\overline{W E}$ and $\overline{B W S}_{\mathrm{X}} \cdot \overline{\mathrm{BWS}}_{\mathrm{X}}=$ Valid signifies that the desired byte Write selects are asserted. See Write Cycle Description table for details.
3. The $D Q$ and $D P$ pins are controlled by the current cycle and the $\overline{\mathrm{OE}}$ signal.
4. $\mathrm{CEN}=1$ inserts wait states.
5. Device will power-up deselected and I/Os in a three-state condition, regardless of $\overline{\mathrm{OE}}$.
6. OE assumed LOW.

## Sleep Mode

The ZZ input pin is an asynchronous input. Asserting ZZ places the SRAM in a power conservation "sleep" mode. Two clock cycles are required to enter into or exit from this "sleep" mode. While in this mode, data integrity is guaranteed. Accesses pending when entering the "sleep" mode are not
considered valid nor is the completion of the operation guaranteed. The device must be deselected prior to entering the "sleep" mode. $\overline{\mathrm{CEs}}, \overline{\mathrm{ADSP}}$, and ADSC must remain inactive for the duration of $\mathrm{t}_{\text {ZZREC }}$ after the ZZ input returns LOW.

## IEEE 1149.1 Serial Boundary Scan (JTAG)

The CY7C1371B/CY7C1373B incorporates a serial boundary scan Test Access Port (TAP) in the BGA package only. The TQFP package does not offer this functionality. This port operates in accordance with IEEE Standard 1149.1-1900, but does not have the set of functions required for full 1149.1 compliance. These functions from the IEEE specification are excluded because their inclusion places an added delay in the critical speed path of the SRAM. Note that the TAP controller functions in a manner that does not conflict with the operation of other devices using 1149.1 fully compliant TAPs. The TAP operates using JEDEC standard 2.5 V I/O logic levels.

## Disabling the JTAG Feature

It is possible to operate the SRAM without using the JTAG feature. To disable the TAP controller, TCK must be tied LOW $\left(\mathrm{V}_{\mathrm{SS}}\right)$ to prevent clocking of the device. TDI and TMS are internally pulled up and may be unconnected. They may alternately be connected to $\mathrm{V}_{\mathrm{DD}}$ through a pull-up resistor. TDO should be left unconnected. Upon power-up, the device will come up in a reset state which will not interfere with the operation of the device.

## Test Access Port - Test Clock

The test clock is used only with the TAP controller. All inputs are captured on the rising edge of TCK. All outputs are driven from the falling edge of TCK.

## Test Mode Select

The TMS input is used to give commands to the TAP controller and is sampled on the rising edge of TCK. It is allowable to leave this pin unconnected if the TAP is not used. The pin is pulled up internally, resulting in a logic HIGH level.

## Test Data In (TDI)

The TDI pin is used to serially input information into the registers and can be connected to the input of any of the registers. The register between TDI and TDO is chosen by the instruction that is loaded into the TAP instruction register. For information on loading the instruction register, see the TAP Controller State Diagram. TDI is internally pulled up and can be unconnected if the TAP is unused in an application. TDI is connected to the most-significant bit (MSB) on any register.

## Test Data Out (TDO)

The TDO output pin is used to serially clock data-out from the registers. The output is active depending upon the current state of the TAP state machine (See TAP Controller State diagram). The output changes on the falling edge of TCK. TDO is connected to the least-significant bit (LSB) of any register.

## Performing a TAP Reset

A Reset is performed by forcing TMS HIGH ( $\mathrm{V}_{\mathrm{DD}}$ ) for five rising edges of TCK. This RESET does not affect the operation of the SRAM and may be performed while the SRAM is operating. At power-up, the TAP is reset internally to ensure that TDO comes up in a High-Z state.

## TAP Registers

Registers are connected between the TDI and TDO pins and allow data to be scanned into and out of the SRAM test circuitry. Only one register can be selected at a time through
the instruction registers. Data is serially loaded into the TDI pin on the rising edge of TCK. Data is output on the TDO pin on the falling edge of TCK.

## Instruction Register

Three-bit instructions can be serially loaded into the instruction register. This register is loaded when it is placed between the TDI and TDO pins as shown in the TAP Controller Block diagram. Upon power-up, the instruction register is loaded with the IDCODE instruction. It is also loaded with the IDCODE instruction if the controller is placed in a reset state as described in the previous section.
When the TAP controller is in the CaptureIR state, the two least significant bits are loaded with a binary "01" pattern to allow for fault isolation of the board level serial test path.

## Bypass Register

To save time when serially shifting data through registers, it is sometimes advantageous to skip certain states. The bypass register is a single-bit register that can be placed between TDI and TDO pins. This allows data to be shifted through the SRAM with minimal delay. The bypass register is set LOW $\left(\mathrm{V}_{\mathrm{SS}}\right)$ when the BYPASS instruction is executed.

## Boundary Scan Register

The boundary scan register is connected to all the I/O pins on the SRAM. Several no connect (NC) pins are also included in the scan register to reserve pins for higher density devices. The $\times 36$ configuration has a 70 -bit-long register, and the $\times 18$ configuration has a 51 -bit-long register.
The boundary scan register is loaded with the contents of the RAM I/O ring when the TAP controller is in the Capture-DR state. It is then placed between the TDI and TDO pins when the controller is moved to the Shift-DR state. The EXTEST, SAMPLE/PRELOAD and SAMPLE Z instructions can be used to capture the contents of the I/O ring.
The Boundary Scan Order tables show the order in which the bits are connected. Each bit corresponds to one of the bumps on the SRAM package. The MSB of the register is connected to TDI, and the LSB is connected to TDO.

## Identification (ID) Register

The ID register is loaded with a vendor-specific, 32-bit code during the Capture-DR state when the IDCODE command is loaded in the instruction register. The IDCODE is hardwired into the SRAM and can be shifted out when the TAP controller is in the Shift-DR state. The ID register has a vendor code and other information described in the Identification Register Definitions table.

## TAP Instruction Set

Eight different instructions are possible with the three-bit instruction register. All combinations are listed in the Instruction Code table. Three of these instructions are listed as RESERVED and should not be used. The other five instructions are described in detail below.
The TAP controller used in this SRAM is not fully compliant with the 1149.1 convention because some of the mandatory 1149.1 instructions are not fully implemented. The TAP controller cannot be used to load address, data, or control signals into the SRAM, and cannot preload the I/O buffers. The SRAM does not implement the 1149.1 commands EXTEST or

INTEST or the PRELOAD portion of SAMPLE/PRELOAD; rather it performs a capture of the I/O ring when these instructions are executed.
Instructions are loaded into the TAP controller during the Shift-IR state when the instruction register is placed between TDI and TDO (during this state, instructions are shifted through the instruction register through the TDI and TDO pins). To execute the instruction once it is shifted in, the TAP controller needs to be moved into the Update-IR state.

## EXTEST

EXTEST is a mandatory 1149.1 instruction that is to be executed whenever the instruction register is loaded with all Os. EXTEST is not implemented in the TAP controller, and therefore this device is not compliant with the 1149.1 standard.
The TAP controller does recognize an all-0 instruction. When an EXTEST instruction is loaded into the instruction register, the SRAM responds as if a SAMPLE/PRELOAD instruction has been loaded. There is one difference between the two instructions: unlike the SAMPLE/PRELOAD instruction, EXTEST places the SRAM outputs in a High-Z state.

## IDCODE

The IDCODE instruction causes a vendor-specific, 32 -bit code to be loaded into the instruction register. It also places the instruction register between the TDI and TDO pins and allows the IDCODE to be shifted out of the device when the TAP controller enters the Shift-DR state. The IDCODE instruction is loaded into the instruction register upon power-up or whenever the TAP controller is given a test logic reset state.

## SAMPLE Z

The SAMPLE Z instruction causes the boundary scan register to be connected between the TDI and TDO pins when the TAP controller is in a Shift-DR state. It also places all SRAM outputs into a High-Z state.

## SAMPLE/PRELOAD

SAMPLE/PRELOAD is a 1149.1-mandatory instruction. The PRELOAD portion of this instruction is not implemented, so the TAP controller is not fully 1149.1 compliant.

When the SAMPLE/PRELOAD instructions loaded into the instruction register and the TAP controller in the Capture-DR state, a snapshot of data on the I/O pins is captured in the boundary scan register.
The user must be aware that the TAP controller clock can only operate at a frequency up to 10 MHz , while the SRAM clock operates more than an order of magnitude faster. Because there is a large difference in the clock frequencies, it is possible that during the Capture-DR state, an input or output will undergo a transition. The TAP may then try to capture a signal while in transition (metastable state). This will not harm the device, but there is no guarantee as to the value that will be captured. Repeatable results may not be possible.
To guarantee that the boundary scan register will capture the correct value of a signal, the SRAM signal must be stabilized long enough to meet the TAP controller's capture set-up plus hold times (TCS and TCH). The SRAM clock input might not be captured correctly if there is no way in a design to stop (or slow) the clock during a SAMPLE/PRELOAD instruction. If this is an issue, it is still possible to capture all other signals and simply ignore the value of the CK and CK\# captured in the boundary scan register.
Once the data is captured, it is possible to shift out the data by putting the TAP into the Shift-DR state. This places the boundary scan register between the TDI and TDO pins.
Note that since the PRELOAD part of the command is not implemented, putting the TAP into the Update to the Update-DR state while performing a SAMPLE/PRELOAD instruction will have the same effect as the Pause-DR command.

## Bypass

When the BYPASS instruction is loaded in the instruction register and the TAP is placed in a Shift-DR state, the bypass register is placed between the TDI and TDO pins. The advantage of the BYPASS instruction is that it shortens the boundary scan path when multiple devices are connected together on a board.

## Reserved

These instructions are not implemented but are reserved for future use. Do not use these instructions.

## TAP Controller State Diagram

Note:
7. The $0 / 1$ next to each state represents the value at TMS at the rising edge of TCK.

## TAP Controller Block Diagram

TAP Electrical Characteristics Over the Operating Range ${ }^{[8,9]}$

| Parameter | Description | Test Conditions | Min. | Max. | Unit |
| :--- | :--- | :--- | :---: | :---: | :---: |

## Notes:

12. $\mathrm{T}_{\mathrm{A}}$ is the case temperature.
13. Minimum voltage equals -2.0 V for pulse durations of less than 20 ns .
14. The load used for $\mathrm{V}_{\mathrm{OH}}$ and $\mathrm{V}_{\mathrm{OL}}$ testing is shown in figure (b) of AC Test Loads.
15. Power Supply ramp up should be monotonic.

Capacitance ${ }^{[16]}$

| Parameter | Description | Test Conditions | Max. | Unit |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{C}_{\mathrm{IN}}$ | Input Capacitance | $\begin{aligned} & \mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{f}=1 \mathrm{MHz}, \\ & \mathrm{~V}_{\mathrm{DD}}=\mathrm{V}_{\mathrm{DDQ}}=2.5 \mathrm{~V} \end{aligned}$ | 3 | pF |
| $\mathrm{C}_{\text {CLK }}$ | Clock Input Capacitance |  | 3 | pF |
| $\mathrm{C}_{\text {/ }}$ | I/O Capacitance |  | 3 | pF |

## AC Test Loads and Waveforms

| $\mathrm{t}_{\text {CEH }}$ | Chip Select Hold After CLK Rise | 0.5 |  | 0.5 |  | 0.5 |  | ns |

Notes:
18. Unless otherwise noted, test conditions assume signal transition time of 2.5 ns or less, timing reference levels of 1.5 V , input pulse levels of 0 to 3.0 V , and output loading of the specified $\mathrm{I}_{\mathrm{L}} / \mathrm{I}_{\mathrm{OH}}$ and load capacitance. Shown in (a), (b) and (c) of AC Test Loads.
19. $t_{\text {CHZ }}, t_{\text {CLZ }}, t_{E O V}, t_{E O L Z}$, and $t_{E O H Z}$ are specified with AC test conditions shown in part (a) of AC Test Loads. Transition is measured $\pm 200 \mathrm{mV}$ from steady-state voltage.
20. At any given voltage and temperature, $t_{E O H Z}$ is less than $t_{E O L Z}$ and $t_{C H Z}$ is less than $t_{C L Z}$ to eliminate bus contention between SRAMs when sharing the same data bus. These specifications do not imply a bus contention condition, but reflect parameters guaranteed over worst case user conditions. Device is designed to achieve High-Z prior to Low-Z under the same system conditions.
21. This parameter is sampled and not $100 \%$ tested.

## Switching Waveforms

Read/Write/Deselect Sequence

The combination of WE and BWSx ( $x=a, b, c, d$ ) to define a Write cycle (see Write Cycle Description table).
CE is the combination of CE1, CE2, and CE3. All chip selects need to be active in order to select the device. Any chip select can deselect the device. RAx stands for Read Address X, WA stands for Write Address X, Dx stands for Data-in X, Qx stands for Data-out X.

## Switching Waveforms (continued)

The combination of WE and BWSx ( $\mathrm{x}=\mathrm{a}, \mathrm{b}, \mathrm{c}, \mathrm{d}$ ) define a Write cycle (see Write Cycle Description table).
CE is the combination of CE1, CE2, and CE3. All chip enables need to be active in order to select the device. Any chip enable can deselect the device. RAx stands for Read Address X, WA stands for Write Address X, Dx stands for Data-in for location X, Qx stands for Data-out for location X. CEN held LOW. During burst writes, byte writes can be conducted by asserting the appropriate BWSx input signals.
Burst order determined by the state of the MODE input. CEN held LOW. OE held LOW.
$\square=$ Don't Care $=$ Undefined

Switching Waveforms (continued)

## $\overline{\mathrm{OE}}$ Timing

ZZ Mode Timing ${ }^{[22,23]}$

## Notes:

22. Device must be deselected when entering ZZ mode. See Cycle Descriptions Table for all possible signal conditions to deselect the device.
23. I/Os are in three-state when exiting ZZ sleep mode.
