

3.3 V, 50 Mbps to 4.25 Gbps, Single-Loop, Laser Diode Driver

Data Sheet ADN2871

FEATURES

SFP/SFF and SFF-8472 MSA-compliant
SFP reference design available
50 Mbps to 4.25 Gbps operation
Automatic average power control
Typical 60 ps rise/fall time
VCSEL, DFB, and FP laser support
Bias current range: 2 mA to 100 mA
Modulation current range: 5 mA to 90 mA
Laser fail alarm and automatic laser shutdown (ALS)
Bias and modulation current monitoring
3.3 V supply
4 mm × 4 mm LFCSP
Voltage setpoint control
Resistor setpoint control
Pin-compatible with ADN2870

APPLICATIONS

1×/2×/4× Fibre Channel SFP/SFF modules Multirate OC3 to OC48-FEC SFP/SFF modules LX-4 modules DWDM/CWDM SFP modules 1GE SFP/SFF transceiver modules VCSEL, DFB, and FP transmitters

GENERAL DESCRIPTION

The ADN2871 laser diode driver (LDD) is designed for advanced SFP and SFF modules, using SFF-8472 digital diagnostics. The ADN2871 supports operation from 50 Mbps up to 4.25 Gbps.

Average power and extinction ratios can be set with a voltage provided by a microcontroller DAC or by a trimmable resistor or digital potentiometer. The average power control loop is implemented using feedback from a monitor photodiode. The device provides bias and modulation current monitoring, as well as fail alarms and automatic laser shutdown (ALS). The device interfaces easily with the Analog Devices, Inc., ADuC7019 and ADuC7020 family of MicroConverter* devices and with the ADN2890, ADN2891, and ADN2892 family of limiting amplifiers to make a complete SFP/SFF transceiver solution. An SFP reference design is available.

The product is pin-compatible with the ADN2870 dual-loop LDD, allowing the same design to work with either device. For dual-loop control applications, refer to the ADN2870 data sheet. The product is available in a space-saving 4 mm \times 4 mm LFCSP specified over the -40° C to $+85^{\circ}$ C temperature range.

Figure 1 shows an application diagram of the voltage setpoint control with single-ended laser interface. Figure 36 shows a differential-ended laser interface.

 $^{^{\}rm 1}$ Power consumption equations are provided in the Power Consumption section.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

 $^{^2\,\}theta_{\text{JA}}$ is defined when the device is soldered on a 4-layer board.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

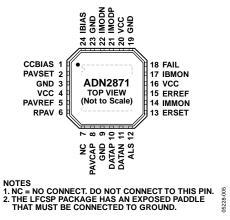

Figure 6. Pin Configuration—Top View

Table 4. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	CCBIAS	In ac-coupled mode, CCBIAS can connect to either IBIAS or VCC. In dc-coupled mode, CCBIAS can connect to VCC.
2	PAVSET	Average Optical Power Set Pin.
3	GND	Supply Ground.
4	VCC	Supply Voltage.
5	PAVREF	Reference Voltage Input for Average Optical Power Control.
6	RPAV	Average Power Resistor when Using PAVREF.
7	NC	No Connect.
8	PAVCAP	Average Power Loop Capacitor.

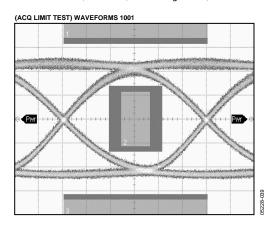

Figure 27. Optical Eye 2.488 Gbps, 65 ps/DIV, PRBS 2^{31-1} $P_{AV} = -0.2$ dBm, ER = 8.96 dB, Mask Margin 21%, $T_A = 85^{\circ}$ C

THEORY OF OPERATION

Laser diodes have a current-in to light-out transfer function, as shown in Figure 28. Two key characteristics of this transfer function are the threshold current, Ith, and the slope in the linear region beyond the threshold current, referred to as the slope efficiency, LI.

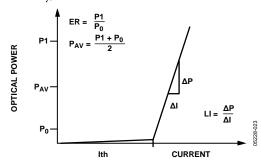

Figure 28. Laser Transfer Function

LASER CONTROL

Typically, laser threshold current and slope efficiency are both functions of temperature. For FP- and DFB-type lasers, the threshold current increases and the slope efficiency decreases with increasing temperature. In addition, these parameters vary as the laser ages. To maintain a constant optical average power and a constant optical extinction ratio over temperature and laser lifetime, it is necessary to vary the applied electrical bias current and modulation current to compensate for the changing LI characteristics of the laser.

Average Power Control Loop (APCL)

The APCL compensates for changes in Ith and LI by varying IBIAS. Average power control is performed by measuring the MPD current, I_{MPD} . This current is bandwidth-limited by the MPD. This is not a problem because the APCL is required to respond to the average current from the MPD.

Extinction Ratio (ER) Control

ER control is implemented by adjusting the modulation current. Temperature calibration is required to adjust the modulation current to compensate for variations of the laser characteristics with temperature.

CONTROL METHODS

The ADN2871 has two methods for setting the average power (P_{AV}) and extinction ratio (ER). The average power and extinction ratio can be voltage-set using the output of a microcontroller's voltage DACs to provide controlled reference voltages, PAVREF and ERREF. Alternatively, the average power and extinction ratio can be resistor-set using potentiometers at the PAVSET and ERSET pins, respectively.

VOLTAGE SETPOINT CALIBRATION

The ADN2871 allows interface to a microcontroller for both control and monitoring (see Figure 29). The average power and extinction ratio can be set using the microcontroller DACs to provide controlled reference voltages, PAVREF and ERREF.

$$PAVREF = P_{AV} \times R_{SP} \times R_{PAV} \tag{V}$$

$$ERREF = \frac{I_{MOD} \times R_{ERSET}}{100} \tag{V}$$

where:

 R_{SP} is the MPD optical responsivity (in amperes per watt). P_{AV} is the average power required.

 $R_{PAV} = R_{ERSET} = 1 \text{ k}\Omega.$

 I_{MOD} is the modulation current.

In voltage setpoint mode, R_{PAV} and R_{ERSET} must be 1 k Ω resistors with a 1% tolerance and a temperature coefficient of 50 ppm/°C.

Power-On Sequence in Voltage Setpoint Mode

During power-up, the ADN2871 goes through its programmed power-up sequence allowing 25 ms before enabling the alarms. Therefore, it is important to ensure the programmed voltages for PAVREF and ERREF are active within 20 ms after ramp-up of the power supply. If no PAVREF and ERREF voltages are applied before the enabled alarms, the ADN2871 alarms and FAIL detection circuits activate and report errors.

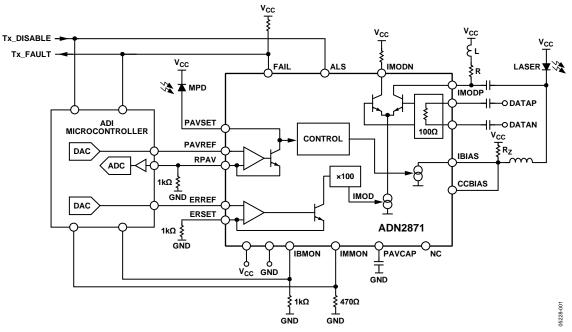

Figure 29. ADN2871 Using Microconverter Voltage Setpoint Calibration and Monitoring

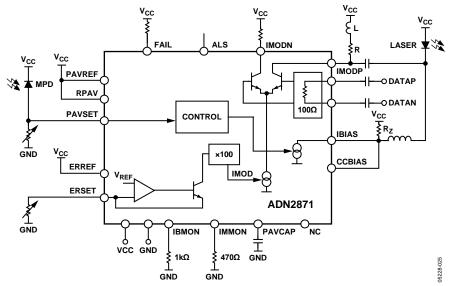

Figure 30. ADN2871 Using Resistor Setpoint Calibration of Average Power and Extinction Ratio

RESISTOR SETPOINT CALIBRATION

In resistor setpoint calibration, Pin PAVREF, Pin ERREF, and Pin RPAV must all be tied to VCC. The average power and extinction ratio can be set using the PAVSET and ERSET pins, respectively. A resistor placed between the pin and GND sets the current flow-ing in each pin, as shown in Figure 30. The ADN2871 ensures that both PAVSET and ERSET are kept 1.23 V above GND. The PAVSET and ERSET resistors are given by

$$R_{PAVSET} = \frac{1.23 \text{ V}}{P_{AV} \times R_{SP}} \tag{\Omega}$$

$$R_{ERSET} = \frac{1.23 \text{ V} \times 100}{I_{MOD}} \tag{\Omega}$$

where:

 R_{SP} is the optical responsivity (in amperes per watt). I_{MOD} is the modulation current required (mA). P_{AV} is the average power required (mW).

Power-On Sequence in Resistor Setpoint Mode

After power-on, the ADN2871 starts an initial calibration processes that takes 25 ms before enabling the alarms. Therefore, the resistors connected to Pin PAVSET and Pin ERSET must stabilize within 20 ms after power-on. If the PAVSET and ERSET resistors do not stabilize within 20 ms after turning on the power supply, the ADN2871 alarm turns on and asserts a FAIL.

IMPD MONITORING

In both voltage setpoint and resistor setpoint modes, several optional I_{MPD} monitoring setups are available as described in the following sections.

Voltage Setpoint

There are two $I_{\mbox{\scriptsize MPD}}$ monitoring methods used in voltage setpoint calibration.

Method 1: Measuring Voltage at RPAV

The I_{MPD} current is equal to the voltage at RPAV divided by the value of RPAV (see Figure 31) as long as the laser is on and is under the control of the ADN 2871. This method does not provide a valid I_{MPD} reading when the laser is in shutdown or fail mode. A MicroConverter buffered ADC input can be connected to RPAV to make this measurement. No decoupling or filter capacitors must be placed on the RPAV node because this can disturb the control loop.

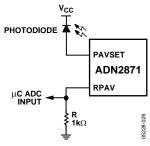

Figure 31. Single Measurement of I_{MPD} at RPAV in Voltage Setpoint Mode

Method 2: Measuring I_{MPD} Across a Sense Resistor

The second method has the advantage of providing a valid I_{MPD} reading at all times, but has the disadvantage of requiring a differential measurement across a sense resistor directly in series with the IMPD. As shown in Figure 32, a small resistor, Rx, is placed in series with the IMPD. If the laser used in the design has a pinout where the monitor photodiode cathode and the lasers anode are not connected, a sense resistor, Rx, can be placed in series with the photodiode cathode and V_{CC}, as shown in Figure 33. When choosing the value of the resistor, the user must take into account the expected I_{MPD} value in normal operation. The resistor must be large enough to make a significant signal for the buffered ADC to read, but small enough not to cause a significant voltage reduction across the PAVSET to ground. The voltage across the sense resistor must not exceed 250 mV when the laser is in normal operation. It is recommended that a 10 pF capacitor be placed in parallel with the sense resistor.

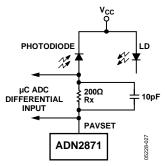

Figure 32. Differential Measurement of IMPD Across a Sense Resistor

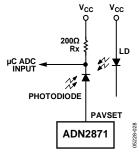

Figure 33. Single Measurement of IMPD across a Sense Resistor

Resistor Setpoint

In resistor setpoint calibration, the current through the resistor from PAVSET to ground is the I_{MPD} current. The recommended method for measuring the I_{MPD} current is to place a small resistor in series with the PAVSET resistor (or potentiometer) and measure the voltage across this resistor, as shown in Figure 34. The I_{MPD} current is then equal to this voltage divided by the value of resistor used. In resistor setpoint calibration, PAVSET is held to 1.2 V nominal; it is recommended that the sense resistor be selected so that the voltage across the sense resistor does not exceed 250 mV.

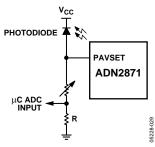

Figure 34. Single Measurement of IMPD Across a Sense Resistor in Resistor Setpoint IMPD Monitoring

LOOP BANDWIDTH SELECTION

To ensure that the ADN2871 control loop has sufficient bandwidth, the average power loop capacitor (PAVCAP) is calculated using the laser slope efficiency (watts/amps) and the average power required.

For resistor setpoint control:

$$PAVCAP = 3.2 \times 10^{-6} \times \frac{LI}{P_{AV}}$$
 (Farad)

For voltage setpoint control:

$$PAVCAP = 1.28 \times 10^{-6} \times \frac{LI}{P_{AV}}$$
 (Farad)

where:

 P_{AV} is the average power required (mW).

LI is the typical slope efficiency at 25°C of a batch of lasers that are used in a design (mW/mA).

LI can be calculated as

$$LI = \frac{P1 - P0}{I_{MOD}}$$
 (mW/mA)

where:

P1 is the optical power at the one level (mW).

P0 is the optical power at the zero level (mW).

The capacitor value equation gets a centered value for the particular type of laser that is used in a design and an average power setting. The laser LI not defined anywhere can vary by a factor of 7 between different physical lasers of the same type and across temperatures without the need to recalculate the PAVCAP value.

This capacitor is placed between the PAVCAP pin and ground. It is important that the capacitor is a low leakage, multilayer ceramic type with an insulation resistance greater than 100 G Ω or a time constant of 1000 seconds, whichever is less. Pick a standard off-the-shelf capacitor value such that the actual capacitance is within $\pm 30\%$ of the calculated value after the capacitor's own tolerance is taken into account.

POWER CONSUMPTION

The ADN2871 die temperature must be kept below 125°C. The LFCSP has an exposed paddle, which must be connected so that it is at the same potential as the ADN2871 ground pins. Power consumption can be calculated as

$$\begin{split} I_{CC} &= I_{CC} \ typ + 0.3 \ I_{MOD} \\ P &= V_{CC} \times I_{CC} + (I_{BIAS} \times V_{BIAS_PIN}) + I_{MOD} \ (V_{MODP_PIN} + V_{MODN_PIN})/2 \\ T_{DIE} &= T_{AMBIENT} + \theta_{JA} \times P \end{split}$$

Thus, the maximum combination of I_{BIAS} + I_{MOD} must be calculated, where:

 I_{CC} typ = 32 mA, the typical value of I_{CC} provided in Table 1 with $I_{BIAS} = I_{MOD} = 0$.

 T_{DIE} is the die temperature.

 $T_{AMBIENT}$ is the ambient temperature.

 V_{BIAS_PIN} is the voltage at the IBIAS pin.

 V_{MODP_PIN} is the voltage at the IMODP pin.

 V_{MODN_PIN} is the voltage at the IMODN pin.

AUTOMATIC LASER SHUTDOWN (Tx DISABLE)

ALS (Tx_DISABLE) is an input that shuts down the transmitter's optical output. The ALS pin is pulled up internally with a 6 k Ω resistor and conforms to SFP MSA specifications. When ALS is logic high or when open, both the bias and modulation currents are turned off. If an alarm has triggered, and the bias and modulation currents are turned off, ALS can be brought high and then low to clear the alarm.

BIAS AND MODULATION MONITOR CURRENTS

IBMON and IMMON are current-controlled current sources that mirror a ratio of the bias and modulation current. The monitor bias current (IBMON) and the monitor modulation current (IMMON) must both be connected to ground through a resistor to provide a voltage proportional to the bias current and modulation current, respectively. When using a microcontroller, the voltage developed across these resistors can be the input to two of the ADC channels, making available a digital representation of the bias and modulation current.

DATA INPUTS

Data inputs must be ac-coupled (10 nF capacitors are recommended) and are terminated via a 100 Ω internal resistor between the DATAP and DATAN pins. A high impedance circuit sets the common-mode voltage and is designed to allow maximum input voltage headroom over temperature. It is necessary to use ac coupling to eliminate the need for matching between common-mode voltages.

LASER DIODE INTERFACING

Figure 35 shows the recommended circuit for interfacing the ADN2871 to most TO-Can or coax lasers. DFB and FP lasers typically have impedances of 5 Ω to 7 Ω and have axial leads. The circuit shown works over the full range of data rates from 155 Mbps to 3.3 Gbps, including multirate operation (with no change to PAVCAP and ERCAP values); see Figure 23, Figure 24, and Figure 25 section for multirate performance examples. Coax lasers have special characteristics that make them difficult to interface to. They tend to have higher inductance, and their impedance is not well controlled. The circuit in Figure 35 operates by deliberately misterminating the transmission line on the laser side while providing a very high quality matching network on the driver side.

The impedance of the driver side matching network is very flat in comparison to frequency and enables multirate operation. A series damping resistor must not be used.

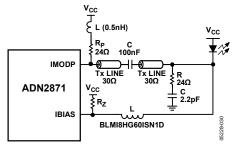

Figure 35. Recommended Interface for ADN2871 AC Coupling

The 30 Ω transmission line used is a compromise between drive current required and the total power consumed. Other transmission line values can be used, with some modification of the component values. In Figure 35, the R and C snubber values, 24 Ω and 2.2 pF respectively, represent a starting point and must be tuned for the particular model of laser being used. R_P, the pull-up resistor, is in series with a very small (0.5 nH) inductor. In some cases, an inductor is not required or can be accommodated with deliberate parasitic inductance, such as a thin trace or a via placed on the PC board.

Take care to mount the laser as close as possible to the PC board, minimizing the exposed lead length between the laser can and the edge of the board. The axial lead of a coax laser is very inductive (approximately 1 nH per mm). Long exposed leads result in slower edge rates and reduced eye margin.

Recommended component layouts and Gerber files are available by contacting Sales at Analog Devices. Note that the circuit in Figure 35 can supply up to 56 mA of modulation current to the laser, sufficient for most lasers available today. Higher currents can be accommodated by changing transmission lines and backmatch values. Contact Sales for recommendations. This interface circuit is not recommended for butterfly-style lasers or other lasers with 25 Ω characteristic impedance. Instead, a 25 Ω transmission line and inductive (instead of resistive) pull-up is recommended.

The ADN2871 single-ended application shown in Figure 35 is recommended for use up to 2.7 Gbps. From 2.7 Gbps to 4.25 Gbps, a differential drive is recommended when driving VCSELs or lasers that have slow fall times. Differential drive can be implemented by adding a few extra components. A possible implementation is shown in Figure 36. The bias and modulation currents that are programmed into the ADN2871 need to be larger than the bias and modulation current required at the laser due to the laser ac coupling interface and because some modulation current flows in pull-up Resistors R1 and R2.

In both circuits shown in Figure 35 and Figure 36, Resistor R_Z is required to achieve optimum eye quality. The recommended R_Z value is approximately 200 $\Omega\sim500~\Omega.$

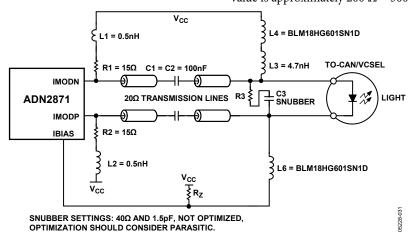

Figure 36. Recommended Differential Drive Circuit

ALARMS

The ADN2871 has a latched, active high monitoring alarm (FAIL). The FAIL alarm output is an open drain in conformance to SFP MSA specification requirements.

The ADN2871 has a three-fold alarm system that covers

- Use of a bias current higher than expected, most likely as a result of laser aging.
- Out-of-bounds average voltage at the monitor photodiode (MPD) input, indicating an excessive amount of laser power or a broken loop.
- Undervoltage in the IBIAS node (laser diode cathode) that increases the laser power.

The bias current alarm trip point is set by selecting the value of resistor on the IBMON pin to GND. The alarm is triggered when the voltage on the IBMON pin goes above 1.2 V. FAIL is activated when the single-point faults in Table 5 occur.

The circuit in Figure 37 can indicate that FAIL has been activated while allowing the bias and modulation currents to remain on. The transistor's V_{BE} clamps the FAIL voltage to below 1.3 V disabling the automatic shutdown of bias and modulation currents. If an alarm has triggered and FAIL is activated, ALS can be brought high and then low to clear the alarm.

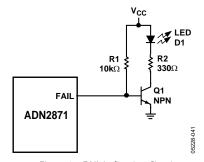

Figure 37. FAIL Indication Circuit

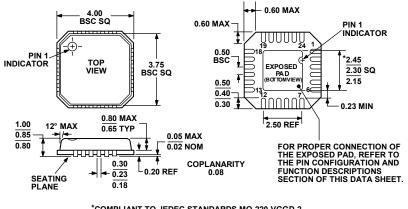

Table 5. ADN2871 Single-Point Alarms

Alarm Type	Mnemonic	Overvoltage or Short to Vcc Condition	Undervoltage or Short to GND Condition
Bias Current	IBMON	Alarm if > 1.2 V typical (±10% tolerance)	Ignore
MPD Current	PAVSET	Alarm if > threshold (typical threshold: 1.5 V to 2.1 V)	Alarm, if < threshold (typical threshold: 0.6 V to 1.1 V)
Crucial Nodes	ERREF (the ERRREF designed tied to Vcc in resistor setting mode)	Alarm if shorted to V _{CC} (the alarm is valid for voltage setting mode only)	Ignore
	IBIAS	Ignore	Alarm, if shorted to GND

Table 6. ADN2871 Response to Various Single-Point Faults in AC-Coupled Configuration (as shown in Figure 35)

Pin	Short to V _{CC}	Short to GND	Open
CCBIAS	Fault state occurs	Fault state occurs	Does not increase laser average power
PAVSET	Fault state occurs	Fault state occurs	Fault state occurs
PAVREF	Voltage mode: Fault state occurs	Fault state occurs	Fault state occurs
	Resistor mode: Tied to V _{CC}		Circuit designed to tie to V _{CC} in resistor setting mode, so no open case
RPAV	Voltage mode: Fault state occurs	Fault state occurs	Voltage mode: Fault state occurs
	Resistor mode: Tied to V _{CC}		Resistor mode: Does not increase average power
PAVCAP	Fault state occurs	Fault state occurs	Fault state occurs
DATAP	Does not increase laser average power	Does not increase laser average power	Does not increase laser average power
DATAN	Does not increase laser average power	Does not increase laser average power	Does not increase laser average power
ALS	Output currents shut off	Normal currents	Output currents shut off
ERSET	Does not increase laser average power	Does not increase laser average power	Does not increase laser average power
IMMON	Does not affect laser power	Does not increase laser average power	Does not increase laser average power
ERREF	Voltage mode: Fault state occurs	Voltage mode: Does not increase average power	Does not increase laser average power
	Resistor mode: Tied to V _{CC}	Resistor mode: Fault state occurs	
IBMON	Fault state occurs	Does not increase laser average power	Does not increase laser average power
FAIL	Fault state occurs	Does not increase laser average power	Does not increase laser average power
IMODP	Does not increase laser average power	Does not increase laser average power	Does not increase laser average power
IMODN	Does not increase laser average power	Does not increase laser average power	Does not increase laser power
IBIAS	Fault state occurs	Fault state occurs	Fault state occurs
