

CMOS Serial Real-Time Clock With RAM and Power Sense/Control

August 1997

## **Features**

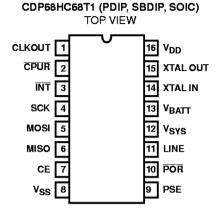

- · SPI (Serial Peripheral Interface)
- Full Clock Features
  - Seconds, Minutes, Hours (12/24, AM/PM), Day of Week, Date, Month, Year (0-99), Automatic Leap Year
- · 32 Word x 8-Bit RAM
- · Seconds, Minutes, Hours Alarm
- · Automatic Power Loss Detection
- · Low Minimum Standby (Timekeeping) Voltage... 2.2V
- · Selectable Crystal or 50/60Hz Line Input
- · Buffered Clock Output
- Battery Input Pin that Powers Oscillator and also Connects to V<sub>DD</sub> Pin When Power Fails
- · Three Independent Interrupt Modes
  - Alarm
  - Periodic
  - Power-Down Sense

# Description

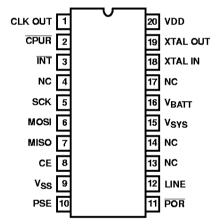

The CDP68HC68T1 Real-Time Clock provides time/calendar function, a 32 byte static RAM, and a 3 wire Serial Peripheral Interface (SPI Bus). The primary function of the clock is to divide down a frequency input that can be supplied by the on-board oscillator in conjunction with an external crystal or by an external clock source. The internal oscillator can operate with a 32KHz, 1MHz, 2MHz, or 4MHz crystal. An external clock source with a 32KHz, 1MHz, 2MHz, 4MHz, 50Hz or 60Hz frequency can be used to drive the CDP68HC68T1. The time registers hold seconds, minutes, and hours, while the calendar registers hold day-ofweek, date, month, and year information. The data is stored in BCD format. In addition, 12 or 24 hour operation can be selected. In 12 hour mode, an AM/PM indicator is provided. The T1 has a programmable output which can provide one of seven outputs for use elsewhere in the system.

Computer handshaking is controlled with a "wired-OR" interrupt output. The interrupt can be programmed to provide a signal as the result of: 1) an alarm programmed to occur at a predetermined combination of seconds, minutes, and hours; 2) one of 15 periodic interrupts ranging from subsecond to once per day frequency; 3) a power fail detect. The PSE output and the V<sub>SYS</sub> input are used for external power control. The CPUR output is available to reset the processor under power-down conditions. CPUR is enabled under software control and can also be activated via the CDP68HC68T1's watchdog. If enabled, the watchdog requires a periodic toggle of the CE pin without a serial transfer.

## NOTES:

- 4. Example: 3:49:18, Tuesday. Oct. 29,1985.
- 5. Most significant Bit, D7, is "0" for 24 hours, and "1" for 12 hour mode. Data Bit D5 is "1" for P.M. and '0" for A.M. in 12 hour mode.
- 6. Alarm hours. Data Bit D5 is "1" for P.M. and "0" for A.M. in 12 hour mode. Data Bits D7 and D6 are DON'T CARE.

# Functional Description

The SPI real-time clock consists of a clock/calendar and a 32 x 8 RAM. Communications is established via the SPI (Serial Peripheral Interface) bus. In addition to the clock/calendar data from seconds to years, and system flexibility provided by the 32-byte RAM, the clock features computer handshaking with an interrupt output and a separate squarewave clock output that can be one of 7 different frequencies. An alarm circuit is available that compares the alarm latches with the seconds, minutes and hours time counters and activates the interrupt output when they are equal. The clock is specifically designed to aid in power-down/up applications and offers several pins to aid the designer of battery backup systems.

#### Mode Select

The voltage level that is present at the V<sub>SYS</sub> input pin at the end of power-on-reset selects the device to be in the single supply or battery backup mode.

## Single-Supply Mode

If  $V_{SYS}$  is a logic high when power-on-reset is completed, CLK OUT, PSE and  $\overline{CPUR}$  will be enabled and the device will be completely operational.  $\overline{CPUR}$  will be placed low if the logic level at the  $V_{SYS}$  pin goes low. If the output signals CLK OUT, PSE and  $\overline{CPUR}$  are disabled due to a power-down instruction,  $V_{SYS}$  brought to a logic low and then to a logic high will re-enable these outputs. An example of the single-supply mode is where only one supply is available and  $V_{DD}$ ,  $V_{BATT}$  and  $V_{SYS}$  are tied together to the supply.

## **Battery Backup Mode**

If  $V_{SYS}$  is a logic low at the end of power-on-reset, CLK OUT, PSE and  $\overline{CPUR}$  will be disabled (CLK OUT, PSE and  $\overline{CPUR}$  low). This condition will be held until  $V_{SYS}$  rises to a threshold (about 0.7V) above  $V_{BATT}$ . The outputs CLK OUT, PSE and  $\overline{CPUR}$  will then be enabled and the device will be operational. If  $V_{SYS}$  falls below a threshold above  $V_{BATT}$  the outputs CLK OUT, PSE and  $\overline{CPUR}$  will be disabled. An example of battery backup operation occurs if  $V_{SYS}$  is tied to  $V_{DD}$  and  $V_{DD}$  is not connected to a supply when a battery is connected to the  $V_{BATT}$  pin. (See Pin Functions,  $V_{BATT}$  for Battery Backup Operation.)

## Clock/Calendar (See Figure 1 and Figure 2)

The clock/calendar portion of this device consists of a long string of counters that is toggled by a 1Hz input. The 1Hz input is generated by a prescaler driven by an on-board oscillator that utilizes one of four possible external crystals or that can be driven by an external clock source. The 1Hz trigger to the counters can also be supplied by a 50Hz or 60Hz input source that is connected to the LINE input pin.

The time counters offer seconds, minutes and hours data in 12 hour or 24 hour format. An AM/PM indicator is available that once set, toggles every 12 hours. The calendar counters consist of day (day of week), date (day of month), month and years information. Data in the counters is in BCD format. The hours counter utilizes BCD for hour data plus bits for 12/24 hour and AM/PM. The 7 time counters are accessed serially at addresses 20H through 26H. (See Table 1).

#### RAM

The real-time clock also has a static 32 x 8 RAM that is located at addresses 00-1FH. Transmitting the address/control word with bit-5 low selects RAM access. Bits 0 through 4 select the RAM location.

#### Alarm

The alarm is set by accessing the three alarm latches and loading the required data. The alarm latches consist of seconds, minutes and hours registers. When their outputs equal the values in the seconds, minutes and hours time counters, an interrupt is generated. The interrupt output will go low if the alarm bit in the Interrupt Control Register is set high. The alarm interrupt bit in the Status Register is set when the interrupt occurs (see Pin Functions,  $\overline{\text{INT}}$  Pin). To preclude a false interrupt when loading the time counters, the alarm interrupt bit should be set low in the Interrupt Control Register. This procedure is not required when the alarm time is

## Watchdog Function (See Figure 6)

When bit 7 in the Interrupt Control Register is set high, the Clock's CE (chip enable) pin must be toggled at a regular interval without a serial data transfer. If the CE is not toggled, the clock will supply a CPU reset pulse and bit 6 in the Status Register will be set. Typical service and reset times are listed below.

	50Hz		60Hz		XTAL	
	MIN	MAX	MIN	MAX	MIN	MAX
Service Time	-	10ms	-	8.3ms	-	7.8ms
Reset Time	20	40ms	16.7	33.3ms	15.6	31.3ms

## Clock Out

The value in the 3 least significant bits of the Clock Control Register selects one of seven possible output frequencies. (See Clock Control Register). This squarewave signal is available at the CLK OUT pin. When Power-Down operation is initiated, the output is set low.

## **Control Registers and Status Registers**

The operation of the Real-Time Clock is controlled by the Clock Control and Interrupt Control Registers. Both registers are Read-Write Registers. Another register, the Status Register, is available to indicate the operating conditions. The Status Register is a Read only Register.

## **Power Control**

Power control is composed of two operations, Power Sense and Power Down/Up. Two pins are involved in power sensing, the LINE input pin and the  $\overline{\text{INT}}$  output pin. Two additional pins are utilized during power-down/up operation. They are the PSE (Power Supply Enable) output pin and  $V_{SYS}$  input pin.

FIGURE 5. POWER-UP FUNCTIONAL DIAGRAM (INITIATED BY INTERRUPT SIGNAL

## Power Sensing (See Figure 3)

When Power Sensing is enabled (Bit 5 = 1 in Interrupt Control Register), AC transitions are sensed at the LINE input pin. Threshold detectors determine when transitions cease. After a delay of 2.68ms to 4.64ms, plus the external input circuit RC time constant, an interrupt is generated and a bit is set in the Status Register. This bit can then be sampled to see if system power has turned back on. See PIN FUNCTIONS, LINE PIN. The power-sense circuitry operates by sensing the level of the voltage presented at the line input pin. This voltage is centered around VDD and as long as it is either plus or minus a threshold (about 1V) from VDD a power-sense failure will not be indicated. With an AC signal present, remaining in this V<sub>DD</sub> window longer than a minimum of 2.68ms will activate the power-sense circuit. The larger the amplitude of the AC signal, the less time it spends in the V<sub>DD</sub> window, and the less likely a power failure will be detected. A 60Hz, 10V<sub>P-P</sub> sinewave voltage is an applicable signal to present at the LINE input pin to setup the power sense function.

## Power Down (See Figure 4)

Power down is a processor-directed operation. A bit is set in the Interrupt Control Register to initiate operation. 3 pins are affected. The PSE (Power Supply Enable) output, normally high, is placed low. The CLK OUT is placed low. The CPUR output, connected to the processors reset input is also placed low. In addition, the Serial Interface is disabled.

#### Power Up (See Figure 5 and Figure 6)

Two conditions will terminate the Power-Down mode. The first condition (See Figure 5) requires an interrupt. The interrupt can be generated by the alarm circuit, the programmable periodic interrupt signal, or the power sense circuit.

The second condition that releases Power Down occurs when the level on the  $V_{SYS}$  pin rises about 0.7V above the level at the  $V_{BATT}$  input, after previously falling to the level of  $V_{BATT}$  (See Figure 6) in the Battery Backup Mode or  $V_{SYS}$  falls to logic low and returns high in the Single Supply Mode.

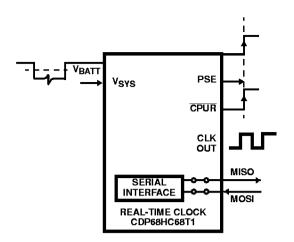

FIGURE 6. POWER-UP FUNCTIONAL DIAGRAM (INITIATED BY A RISE IN VOLTAGE ON THE "V<sub>SYS</sub>" PIN)

#### **CLK OUT**

Clock output pin. One of seven frequencies can be selected (or this output can be set low) by the levels of the three LSB's in the Clock-Control Register. If a frequency is selected, it will toggle with a 50% duty cycle except 2Hz in the 50Hz time base mode. (Ex, if 1Hz is selected, the output will be high for 500ms and low for the same period). During power-down operation (bit 6 in Interrupt Control Register set to "1"), the clock-output pin will be set low.

#### **CPUR**

CPU reset output pin. This pin functions as an N-Channel only, open-drain output and requires an external pull-up resistor.

#### INT

Interrupt output pin. This output is driven from a single NFET pulldown transistor and must be tied to an external pull-up resistor. The output is activated to a low level when:

- Power-sense operation is selected (B5 = 1 in Interrupt Control Register) and a power failure occurs.
- A previously set alarm time occurs. The alarm bit in the Status Register and interrupt-out signal are delayed 30.5μs when 32kHz operation is selected and 15.3μs for 2MHz and 7.6μs for 4MHz.
- 3. A previously selected periodic interrupt signal activates.

The Status Register must be read to set the Interrupt output high after the selected periodic interval occurs. This is also true when conditions 1 and 2 activate the interrupt. If power down had been previously selected, the interrupt will also reset the power-down functions.

## SCK, MOSI, MISO

See Serial Peripheral Interface (SPI) section in this data sheet.

#### CE

A positive chip-enable input. A low level at this input holds the serial interface logic in a reset state. This pin is also used for the watchdog function.

## VSS

The negative power-supply pin that is connected to ground.

#### **PSE**

Power-supply enable output pin. This pin is used to control power to the system. The pin is set high when:

- V<sub>SYS</sub> rises above the V<sub>BATT</sub> voltage after V<sub>SYS</sub> was placed low by a system failure.
- 2. An interrupt occurs.
- A power-on reset (if V<sub>SYS</sub> is a logic high).

The PSE pin is set low by writing a high into bit 6 (power-down bit) in the Interrupt Control Register.

#### POR

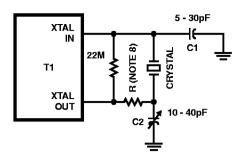

Power-on reset. A Schmitt-trigger input that generates a power-on internal reset signal using an external R-C network. Both control registers and frequency dividers for the oscillator and line input are reset. The Status Register is reset except for the first time up bit (B4), which is set. Single supply or battery backup operation is selected at the end of POR.

#### LINE

This input is used for two functions. When not used it should be connected to  $V_{DD}$  via a  $10 \mathrm{k}\Omega$  resistor. The first function utilizes the input signal as the frequency source for the timekeeping counters. This function is selected by setting bit 6 in the Clock Control Register. The second function enables the line input to sense a power failure. Threshold detectors operating above and below  $V_{DD}$  sense an AC voltage loss. Bit 5 must be set to "1" in the Interrupt Control Register and crystal or external clock source operation is required. Bit 6 in the Clock Control Register must be low to select XTAL operation.

## **Oscillator Circuit**

The CDP68HC68T1 has an on-board 150K resistor that is switched in series with its internal inverter when 32kHz is selected via the Clock Control Register. Note: When first powered up the series resistor is not part of the oscillator circuit. (The CDP68HC68T1 sets up for a 4MHz oscillator).

#### NOTES:

- All frequencies recommended oscillator circuit. C1, C2 values crystal dependent.
- 8. R used for 32KHz operation only. 100K 300K range as specified by crystal manufacturer.

## FIGURE 7. OSCILLATOR CIRCUIT

## VSYS

This input is connected to the system voltage. After the CPU initiates power down by setting bit 6 in the Interrupt Control Register to "1", the level on this pin will terminate power down if it rises about 0.7V above the level at the V<sub>BATT</sub> input pin after previously falling below V<sub>BATT</sub> +0.7V. When power down is terminated, the PSE pin will return high and the Clock Output will be enabled. The CPUR output pin will also return high. The logic level present at this pin at the end of POR determines the CDP68HC68T1's operating mode.

## VBATT

The oscillator power source. The positive terminal of the battery should be connected to this pin. When the level on the V\_{SYS} pin falls below V\_{BATT} +0.7V, the V\_{BATT} pin will be internally connected to the V\_{DD} pin. When the voltage on V\_{SYS} rises a threshold above (0.7V) the voltage on V\_{BATT}, the connection from V\_{BATT} to the V\_{DD} pin is opened. When the "LINE" input is used as the frequency source, V\_{BATT} may be tied to V\_{DD} or V\_{SS}. The "XTAL IN" pin must be at V\_{SS} if V\_{BATT} is at V\_{SS}. If V\_{BATT} is connected to V\_{DD}, the "XTAL IN" pin can be tied to V\_{SS} or V\_{DD}.

## **XTAL IN, XTAL OUT**

These pins are connected to a 32,768Hz. 1.048576MHz, 2.097152MHz or 4.194304MHz crystal. If an external clock is used, it should be connected to "XTAL IN" with 'XTAL OUT" left open.

## $V_{DD}$

The positive power-supply pin.

# Clock Control Register

#### START-STOP

A high written into this bit will enable the counter stages of the clock circuitry. A low will hold all bits reset in the divider chain from 32Hz to 1Hz. A clock out selected by bits 0, 1 and 2 will not be affected by the stop function except the 1Hz and 2Hz outputs.

#### LINE-XTAL

When this bit is set high, clock operation will use the 50 or 60-cycle input present at the LINE input pin. When the bit is low, the crystal input will generate the 1Hz time update.

#### **XTAL Select**

One of 4 possible crystals is selected by value in these two hits:

0 = 4.194304MHz 2 = 1.048576MHz1 = 2.097152MHz 3 = 32,768Hz

#### 50-60Hz

50Hz is selected as the line input frequency when this bit is set high. A low will select 60Hz. The power-sense bit in the Interrupt Control Register must be set low for line frequency operation.

## **Clock Out**

The three bits specify one of the 7 frequencies to be used as the squarewave clock output:

0 = XTAL 4 = Disable (low output) 1 = XTAL/2 5 = 1Hz 2 = XTAL/4 6 = 2Hz 3 = XTAL/8 7 = 50Hz or 60Hz XTAL Operation = 64Hz

All bits are reset by a power-on reset. Therefore, the XTAL is selected as the clock output at this time.

# Interrupt Control Register

## Watchdog

When this bit is set high, the watchdog operation will be enabled. This function requires the CPU to toggle the CE pin periodically without a serial-transfer requirement. In the event this does not occur, a CPU reset will be issued. Status Register must be read before re-enabling watchdog.

## Power Down

A high in this location will initiate a power down. A CPU reset will occur, the CLK OUT and PSE output pins will be set low and the serial interface will be disabled.

## CLOCK CONTROL REGISTER (Write/Read) - Address 31H

D7	D6	D5	D4	D3	D2	D1	D0
START	LINE	XTAL	XTAL	50Hz	CLK OUT	CLK OUT	CLK OUT
		SEL	SEL				
STOP	XTAL	1	0	60Hz	2	1	0

#### **Power Sense**

This bit is used to enable the line input pin to sense a power failure. It is set high for this function. When power sense is selected, the input to the 50Hz to 60Hz prescaler is disconnected. Therefore, crystal operation is required when power sense is enabled. An interrupt is generated when a power failure is sensed and the power sense and Interrupt True bit in the Status Register are set. When power sense is activated, a "0" must be written to this location followed by a "1" to re-enable power sense.

The output of the alarm comparator is enabled when this bit is set high. When a comparison occurs between the seconds, minutes and hours time and alarm counters, the interrupt output is activated. When loading the time counters, this bit should be set low to avoid a false interrupt. This is not required when loading the alarm counters. See Pin Functions, INT for explanation of alarm delay.

## **Periodic Select**

The value in these 4 bits will select the frequency of the periodic output. (See Table 2).

## Alarm

## INTERRUPT CONTROL REGISTER (Write/Read) - Address 32H

D7	D6	D5	D4	D3	D2	D1	D0

15	Day	Х	Х	

## STATUS REGISTER (Read Only) - Address 30H

D7	D6	D5	D4	D3	D2	D1	D0
0	WATCHDOG	TEST MODE	FIRST TIME UP	INTERRUPT TRUE	POWER SENSE INTERRUPT	ALARM INTERRUPT	CLOCK INTERRUPT

#### TRUTH TABLE

	SIGNAL								
MODE	CE	SCK (Note 9)	MOSI	MISO					
DISABLE RESET	L	INPUT DISABLED	INPUT DISABLED	HIGH Z					
WRITE	Н	CPOL = 1  CPOL = 0	DATA BIT LATCH	HIGH Z					
READ	Н	CPOL = 1  CPOL = 0	X	NEXT DATA BIT SHIFTED OUT (Note 10)					

#### NOTES:

- 9. When interfacing to CDP68HC05 microcontrollers, serial clock phase bit, CPHA, must be set = 1 in the microcomputer's Control Register.
- 10. MISO remains at a high Z until 8-bits of data are ready to be shifted out during a READ. It remains at a high Z during the entire WRITE cycle.

#### WATCHDOG

If this bit is set high, the watchdog circuit has detected a CPU failure.

## **TEST MODE**

When this bit is set high, the device is in the TEST MODE.

#### FIRST-TIME UP

Power-on reset sets this bit high. This signifies that data in the RAM and Clock is not valid and should be initialized.

#### INTERRUPT TRUE

A high in this bit signifies that one of the three interrupts (Power Sense, Alarm, and Clock) is valid.

## **POWER-SENSE INTERRUPT**

This bit set high signifies that the power-sense circuit has generated an interrupt.

#### **ALARM INTERRUPT**

When the seconds, minutes and hours time and alarm counter are equal, this bit will be set high. Status Register must be read before loading Interrupt Control Register for valid alarm indication after alarm activates.

#### **CLOCK INTERRUPT**

A periodic interrupt will set this bit high.

All bits are reset by a power-on reset except the "FIRST-TIME UP" which is set. All bits except the power-sense bit are reset after a read of this register.

# Pin Signal Description

## SCK (Serial Clock Input, Note 11)

This input causes serial data to be latched from the MOSI input and shifted out on the MISO output.

#### MOSI (Master Out/Slave In. Note 11)

Data bytes are shifted in at this pin, most significant bit (MSB) first.

## MISO (Master In/Slave Out)

Data bytes are shifted out at this pin, most significant bit (MSB) first.

## CE (Chip Enable, Note 12)

A positive chip-enable input. A low level at this input holds the serial interface logic in a reset state, and disables the output driver at the MISO pin.

#### NOTES

- 11. These inputs will retain their previous state if the line driving them goes into a High-Z state.
- The CE input has as internal pull down device, if the input is in a low state before going to High Z, the input can be left in a High Z.

## Functional Description

The Serial Peripheral Interface (SPI) utilized by the CDP68HC68T1 is a serial synchronous bus for address and data transfers. The clock, which is generated by the microcomputer is active only during address and data transfers. In systems using the CDP68HC05C4 or CDP68HC05D2, the
